# THE DECREASE, RESTORATION, AND PRESERVATION OF SALMON IN CANADA.

BY THE REV. WILLIAM AGAR ADAMSON, D.C.L.

Read before the Canadian Institute, December 6th, 1856.

Brillat Savarin, in his "Physiologie du Gout," asserts that the man who discovers a new dish does more for the happiness of the human race than he who discovered the Georgium Sidus. If this be true, then he who could devise means for the preservation and increase of an old, wholesome and highly coveted article of food would not labor in vain, nor would, I imagine, his endeavors be despised by the members of the Canadian Institute, however humble his abilities, and however unskilled he might be in scientific lore. Actuated by this belief, as well as desirous to respond to the demand for co-operation among the members of the Canadian Institute, I would venture to lay before you some notes upon the decrease, restoration, and preservation of the Salmon (Salmo Salar) in Canada.

It is unnecessary to magnify the importance of this fish as an economic production, or as an article of commerce. As food it is beyond comparison the most valuable of fresh water fish, both on account of the delicacy of its flavor, and the numbers in which it can be supplied. By prudence, a little exertion, and avery small expense now, it may not only be rendered cheap and accessible to almost every family in Canada, but also an article of no small commercial importance as an export to the United States, in which country, by

VOL. II.-A

pursuing the course which Canada has hitherto imitated, this noble fish has been almost exterminated. Twenty-five or thirty years ago every stream tributary to the St. Lawrence, from Niagara to Labrador on the north side, and to Gaspé basin on the south, abounded with salmon. At the present moment, with the exception of a few in the Jacques Cartier, there is not one to be found in any river between the Falls of Niagara and the city of Quebec. This deplorable decrease in a natural production of great value has arisen from two causes ; 1st .- the natural disposition of uncivilized man to destroy at all times and at all seasons whatever has life and is fit for food; and 2nd.-the neglect of those persons who have constructed mill-dams, to attach to them slides, or chutes, by ascending which the fish could pass onwards to their spawning beds in the interior. It is supposed by many that the dust from the sawmills getting into the gills of the salmon prevents them from respirating freely, and so banishes them from the streams on which such mills are situated, but I am persuaded that this is a mistake, for salmon are found in considerable numbers at the mouths of many such streams, below the dams. In the Marguerite, in the Saguenay, at the Petit Saguenays, the Es-quemain, Port Neuf. Rimouski, Metis, and others that might be named, the real cause of the decrease is the insuperable obstacles presented by mill-dams, which prevent them from ascending to the ærated waters, high up the streams, which are essential for the fecundation of their ova, and so for the propagation of the species. Would you then-it may be asked, pull down our mills in order that we might have salmon in our rivers ? most certainly not, I reply, for it is guite possible to maintain all our mills, with all their mill-dams, and yet afford to the fish an easy and inexpensive mode of passing upwards to their breeding places.

Marvellous stories are told of the great heights which salmon will leap in order to surmount the obstacles which nature or art may have erected between the lower parts of a stream and the upper waters which are suited to breeding purposes. Natural historians used gravely to tell us that salmon, in order to jump high, were in the habit of placing their tails in their mouths, and then, bending themselves like a bow, bound out of the water to a considerable distance, from twelve to twenty feet. The late Mr. Scrope, in his beautiful book "Days and Nights of Salmon Fishing," calculates that six feet in height is more than the average spring of salmon, though he conceives that very large fish in deep water, could leap much higher. He says, "Large fish can leap much higher than small ones; but their powers are limited or augmented according to the depth of water they spring from; in shallow water they have little power of ascension, in deep they have the most considerable. They rise very rapidly from the very bottom to the surface of the water by means of rowing and sculling as it were, with their fins and tail, and this powerful impetus bears them upwards in the air, on the same principle that a few tugs of the oar make a boat shoot onwards after one has ceased to row." However this may be, we know that salmon use almost incredible efforts to ascend their native rivers. Modes have recently been adopted in France, in England, Scotland and Ireland, by which they can do so with ease, and which can be much more cheaply applied to Mill-dams in Canada, than in any of the countries above mentioned. This is simply by constructing below each milldam a congeries of wooden boxes proportioned to the height of the dam-which could be done, in any weirs I have seen requiring them, for a sum not exceeding twenty dollars. We will suppose that the mill-dam to be passed over is fifteen feet high from the surface of the water, and that the salmon can surmount the height of five feet at a single bound, then it would be only necessary to erect two boxes, each five feet high, one over the other (as in the illustration) to enable the salmon, in three leaps, to reach the waters which nature prompts him to seek for the propagation of his species. In many Canadian rivers-such as Metis. Matane, Rimouski, Trois Saumons, etc.-this simple apparatus might be put in operation for one half the sum I have mentioned, and I trust it has only to be suggested to the gentlemen residing on their banks to arouse their patriotism and excite them to activity in the matter. There can be no doubt that were the milldams removed, or boxes constructed adjacent to them, and protection afforded to the spawning fish, many of the rivers in Upper Canada would again abound with Salmon. I have myself, within a few years, taken the true Salmo Salar in Lake Ontario, near Kingston, and many persons in Toronto know that they are taken annually at the mouths of the Credit, the Humber and at Bond Head, in the months of May and June, which is earlier than they are generally killed below Quebec. Whether these fish come up the St. Lawrence in the early spring, under the pavement of ice which then rests upon its surface, or whether they have spent the winter in Lake Ontario, is a question which I must leave to naturalists; merely mentioning that there is some foundation for believing that salmon will not only live. but breed, in fresh water, without visiting the sea. Mr. Lloyd, in his interesting work on the field sports of the North of Europe, says,

"Near Katrineberg, there is a valuable fishery for salmon, ten or twelve thousand of these fish being taken annually. These salmon are bred in a lake, and, in consequence of cataracts, cannot have access to the sea. They are small in size and inferior in flavor," which may also be asserted of salmon taken in the neighborhood of Toronto. Mr. Scrope, in his work previously quoted, states that Mr. George Dormer, of Stone Mills, in the Parish of Bridport, put a female of the salmon tribe, which measured twenty inches in length, and was caught by him at his mill-dam, into a small well, where it remained twelve years, became quite tame and familiar, so as to feed from the hand, and was visited by many persons of respectability from Exeter and its neighborhood.

But the fact that salmon are annually taken near the Credit, the Humber and Bond Head is sufficient ground on which to base my argument for the probability that were the tributary streams of the St. Lawrence accessible to them they would ascend and again stock them with a numerous progeny. Even were this found not to be the case,-then we have the system of artificial propagation to fall back upon-a system which according to the Parliamentary Reports of the Fishery Commissioners has been practised with immense success in different parts of Ireland-according to M. Coste, Member of the Institute, and professor of the college of France, in his reports to the French Academy and the French Government, has answered admirably in France, and according to Mr. W. H. Fry and others, quoted by him in his treatise on artificial fish-breeding, has been generally effective in Scotland. This system, as is well known, consists simply of transporting from one river to another the impregnated eggs of the salmon, and placing them in shallow waters with a gentle current where they are soon hatched, and become salmon fry or par and able to take care of themselves. In consequence of the ova of the salmon, which are deposited in the spawning beds in the months of October, November and December, becoming congealed by frost in the subsequent months, Canada appears to offer greater facilities for their safe transport than those countries in which the system has been so successful, but whose climates are more temperate. Surely, supposing this is a mere untried experiment-which is far from being the case-it would be well worth the while of some of the many wealthy and intelligent dwellers upon the banks of our beautiful rivers to test its value, particularly when they call to mind the well known fact in the natural history of the salmon, that he invariably returns to the stream in which his youth was spent, and that so they may calculate

upon having their present barren rivers stocked with as valuable articles of consumption and of commerce as their fowl-houses or their farm-yards.

I shall, for brevity's sake, abstain from enlarging on this subject, merely observing that ample information can be obtained upon it by consulting the works of M.M. Coste and Fry, which are to be found in the libraries and bookshops in this city ; and that in the streams in which it may be put into operation—if there are mill-dams upon them—the artificial construction to enable the fish to descend and ascend to and from the sea will still be requisite.

Having said so much on the decrease and restoration of salmon in Canada, let us now turn our attention for a few moments to their preservation in the rivers in which they still abound. These rivers I believe to be as valuable and inexhaustible as any others upon the face of the globe, but so circumstanced that their capabilities have not been developed, and that one year of neglect will cause their serious injury, if not their utter destruction, as salmon streams. They extend along the northern shore of the St. Lawrence from Quebec to Labrador, a distance of about 500 miles, and are many in number. They are chiefly held under lease from the Government of Canada, by the Hudson's Bay Company, who fish some of them in an unsystematic manner, with standing nets, because they can be conveniently and cheaply so fished, whilst others are left wholly to the destructive spear of the Indian. In the smaller streams on which the fishermen of the company are employed, a series of standing barrier-nets, (which kill indiscriminately every fish of every size and weight,) is used, a process, which in European rivers, would have long since banished salmon from them. But in Canada the high water in the spring enables some of the largest and strongest of the breeding fish to ascend the streams before those nets can be set, and when they get beyond them, they are comparatively safe in the mountain rivers and lakes which never hear a human footfall till winter-which congeals their surfaces into ice-tempts the poor Indian to tread their banks in pursuit of the bear, the marten, the mink and the otter.

In well regulated salmon fisheries in Europe, the fish—by the construction of proper weirs and reservoirs—are almost as much under the control of the managers as the sheep on their farms or the fowl in their poultry-yards. They can send such of them as they please to market, permit the fittest for the purpose to pass on to propagate their kind, allow the young to enjoy life till they become mature, and suffer the sick and unhealthy to return to their invigorating pastures in the depths of the ocean. But no portion of this system is practised in our American rivers. There is not a salmon weir in the province; and the consequence is, that young and old, kelt and grilse, worthless and unwholesome, the fish are killed by the undiscriminating net and the cruel spear.

It appears to me that the Hudson's Bay Company set little value on these fisheries, and maintain them merely as an accident appertaining to the fur trade which is far more profitable. The approaching termination of their lease and the consequent uncertainty of their tenure may perhaps appear a sufficient reason for their not incurring the expense of erecting weirs, by which much more profit could be made of their fisheries. Unproductive and wasteful as their mode of fishing is, the protection the Hudson's Bay Company affords is the only present safequard for the existence of Salmon in Canada. I am persuaded that were that protection withdrawn for ONE SUM-MER, without the substitution of some other as effective, this noble fish would be utterly exterminated from our country. Fishermen from Gaspé, Rimouski, New Brunswick, Labrador, Newfoundland, the Magdalene Islands and the United States-whose numbers and skill would enable them to do thoroughly what the servants of the H. B. C. from their paucity and inexperience do ineffectuallywould swarm up our rivers, and with nets. spears, torches, and every other engine of piscine destruction, would kill, burn and mutilate every fish that ventured into the rivers. Already has this been attempted. For the last two or three years schooners from the United States, have regularly arrived, in the salmon season, at the Bay of Seven Islands, their crews well armed, and have set their nets in the river Moisie, in despite of the officers of the H. B. C. Similar circumstances have occurred at other fishing stations in the tributaries of the St. Lawrence; no means, that I am aware of, having been resorted to for punishing the aggressors or preventing a repetition of their outrages. The river Bersinies has this year (1856) been altogether in the hands of a speculating and rapacious American, who employed the spear of the Indian to furnish him with mutilated salmon, several boxes of which he brought to this city, in the month of September, when they were out of season, unfit for food and flavorless, having previously glutted the markets of Portland, Boston and New York with more palatable fish.

There can be but little doubt that many of the salmon streams in Lower Canada would be as productive, under proper management, as rivers in Europe for which large annual rents are paid; but it must

be admitted that the great distance at which they are situated from Civilization, the want of the means of intercourse between them and the inhabited parts of the country, the liability to trespass by armed ruffians, and the dreadful rigor of the climate in winter, present very serious obstacles to those who might wish to undertake such management : for obviating some of which I see no better method than the employment, during the summer months, of one or two armed steamers of light draught of water, such as are used for a similar purpose on the east coast of Denmark. These steamers should each have a commander on board, who should be a magistrate and empowered by parliament to act summarily in cases of infraction of the Fishery Laws, and beside supplying the lighthouses and other public works with stores, oil, building materials, etc., conveying the workmen managers and fishermen to their several stations, and protecting the lessees of the Province, might also be profitably employed as the means of transporting the fresh caught salmon from the several rivers, packed in ice, to the Rail-road Stations at St. Thomas and Quebec; from whence they could be distributed to the markets of Canada and the United States. Two Bills for the protection of salmon and trout in Lower Canada have recently become Acts of Parliament. These may possibly be productive of some good in civilized and inhabited districts, but must be utterly ineffective in those parts of the Province where there are no settled inhabitants, no magistrates, and no tribunals before which those who infringe the Law can be cited; and this is the case of all the best rivers in Lower Canada.

I cannot close these observations without endeavoring to impress on all who hear me, the necessity for prompt action in this matter; for there can be no doubt upon the mind of any man who is acquaintted with the localities, that if the King's Posts should be abandoned by the Hudson's Bay Company, before some well devised system be adopted for carrying on the work which they have hitherto effected, two melancholy results will be the inevitable consequences, viz.the salmon rivers will be taken possession of by hordes of lawless men, who will in no way contribute to the revenue of the country, but will quickly and recklessly exterminate the fish, and then desert our shores, leaving behind them no trace of their temporary occupation except the destruction they have wrought-and more terrible still-a whole tribe of Indians (the Montagnards) will be reduced to a state of positive starvation, for upon the Hudson's Bay Company they have hitherto been, and are now dependent for their ammunition, guns, and other means by which they obtain their food and clothing.

#### ON PRESERVING TIMBER FROM DECAY.

## ON PRESERVING TIMBER FROM DECAY.

# BY JOSEPH ROBINSON, TORONTO.

### Read before the Canadian Institute, December 20th, 1856.

The economic value of timber, and the immense outlay required for the constant restoration of works executed in the cheaper but least durable varieties of woods, have long directed the attention of practical men to the desirableness of discovering some process by which greater durability could be given to a material, in all other respects so admirably adapted to the objects in view, without affecting its original cost to such an extent as to render it no longer available for the numerous ordinary purposes to which it is now applied. To this subject, attention was anew directed in the last number of the *Canadian Journal*, in an article on the "Preservation of Timber;"\* and it may not be out of place, by way of adding to the existing fund of information upon a subject of such general interest, to bring before the Institute, a well attested and valuable process invented and used by the eminent French chemist, Dr. Boucherie.

This process is the result of twenty years experimental labor and study, and is regarded in France and England as of the highest importance, being the only mode yet brought into practical and extensive application, by which the durability of woods, liable to decay, can be economically and effectually secured.

It accomplishes two objects : first, that of expelling the sap ; and, secondly, filling the pores of the timber with a preservative solution.

The mode of impregnating trees hitherto adopted, has been by saturation only, assisted sometimes by great pressure, and by previously subjecting the timber in cylinders to a vacuum or to heat.

Dr. Boucherie's process differs entirely: inasmuch as he applies a moderate pressure, and to one end only of the sap tubes of the tree, the effect of which is to expel the sap by the preserving liquor which takes its place. By some of the processes hitherto used, the sap (the fermentation of which is admitted to be the cause of decay) is allowed to remain in the tree; in the process now under review, the sap is expelled, and the tubes are thoroughly cleansed from the fermenting matter, which is displaced by an injected solution of a preservative nature.

The tubular structure of trees has been long known, but it has not

8

<sup>\*</sup> Vide Vol. I., p. 559. New Series,

been known that no connexion exists between the tubes laterally; and this is shewn by the interesting experiment of stopping up or shutting off certain of the sap-tubes at the end of the tree, leaving exposed such as form a word : which word, or name, by the injection of a coloring liquor, can be driven from one end of the tree to the other; so that wherever the tree is cut through, the name appears distinctly in colored letters on the exposed sections.

This experiment is interesting, not only in a scientific point of view; but it shews that none of the processes hitherto used, wherein lateral pressure is involved, can force any preserving liquor into a tree without a degree of violence, which must injure the fibre of the wood, and destroy its strength and use for many purposes.

The advantages which would result from expelling the sap and replacing it by an antisceptic fluid, have been long known; and the idea of effecting this by applying the fluid under pressure at the end of a piece of timber is not new, having been suggested and patented many years ago by Mr. Bethel. But the means then used did not accomplish the object in such a manner as to admit of its commercial application. Hence the more expensive process of creosoting has been adopted; where the timber is totally immersed in the oil, under pressure, a method which does not permit the sap to escape.

By the old process of violent pressure, the preserving liquor is forced at right angles to the tubes through the woody fibre of the tree, injuring its strength as well as its capability, in railway sleepers, for example, to resist the wear of the chairs; consuming at the same time an unnecessary amount of the preserving liquor, without (whatever pressure may be applied) thoroughly impregnating the timber, while one-sixth or one-eighth of the force only is necessary by the new process, and the portion alone requiring the preservative infusion, viz. the soft matter between the rings, is impregnated, the woody fibre remaining unbroken and undisturbed.

Another important advantage in Dr. Boucherie's process, is derived from the simplicity and moderate cost of the apparatus, which, for operations on a small scale, will not exceed £10 or £15, and for a railway of two hundred miles, under £50.

The practical application and entire success of this invention in Europe will be seen by the printed official reports. The first of these was made, by order of the French Government, in the year 1850, the second in 1852, and the third in 1856 : being an abstract from the official jury report of the Exposition Universelle of 1855, whereby it will be seen that the distinguished honor of one of the large gold medals was awarded to Dr. Boucherie, of which only four were conferred in all.

The mode of application is as follows :—Soon after the tree is felled, a saw-cut is made in the centre, through about nine-tenths of its section. The tree is slightly raised by a lever or wedge at its centre, and the saw-cut thereby partially opened; a piece of string is then placed round the cut, close to the outer circumference of the tree, the support is withdrawn, and the saw-cut closes on the string, thereby making a water-tight joint. An auger-hole is then bored obliquely into the saw-cut; a wooden tube is driven into the hole, the conical end of which is attached to a flexible pipe, which is in connexion with a cistern or reservoir, at an elevation of from 30 to 40 feet above the tree intended to be preserved.

When it is necessary to prepare timber in long lengths, a cap is placed at the end of the tree by screws or dogs. The most efficacious solution is composed of sulphate of copper and water, mixed in the proportion of 1 to 100. The strength is easily ascertained, by any intelligent workman, by an hydrometer ;—and the cost of such a solution is so trifling, as to offer no impediment to its universal application for the purpose in view.\*

It would be difficult to enumerate all the classes to be benefitted by this invention, and the uses to which it may be applied. Railway companies, ship-builders, telegraph companies, and land owners, would alike benefit by it. Post and rail fencing, field gates, wood farm buildings, frame buildings, and dwellings in general, would last many additional years. Mr. R. Stephenson, the President of the Institute of Civil Engineers, in his inaugural address, adverts to the great consumption of railway sleepers by decay, and estimates it at 2,600,-000 per annum, costing upwards of £500,000. Taking the resistance

<sup>\*</sup> On comparing the above account of Boucherie's process with that described in the *Canadian Journal* (No. 6, pp. 559-561) and for which a patent was taken out in May, 1856, the two processes appear to be identical so far as the employment of hydraulic pressure is concerned, and if such is the case, this part of the patent is void.

The following is the text of the Patent Law bearing upon this point. "If at "the trial in any such action [for infringement of Patent,] it shall be made appa-"rent to the satisfaction of the Court...that the thing thus secured by Patent "was not originally discovered by the Patentee, or party claiming to be the "Inventor or Discoverer in the specification referred to in the Patent, but had "been in use, or had been described in some public work, anterior to the supposed "discovery of the Patentee.....the Patent shall be declared void." 13 and 14 Vict. "79, c. 8.—(Ed. Can. Jour.)

of the proposed sleepers to decay as the only basis of the calculation, a large proportion of this sum would be saved. Assuming the duration of the sleeper to be doubled, and taking into account the mechanical causes of destruction, a saving of  $\pounds 300,000$  per annum, would be effected to the railway interest in England alone.

From these data, the value of the invention in Europe will readily be seen, and although it has been patented in France and England, and, as it would seem, to some extent, in Canada, it is believed that the use in this Province is unfettered; 1st, because by the Statutes of Canada, no foreigner can obtain a patent monopoly in this country; and, 2nd, because, being already known and used in other countries, it cannot be patented here.

# THE CHINOOK INDIANS.

### BY PAUL KANE, TORONTO.

In accordance with an invitation of the Council of the Canadian Institute to communicate notices of some of the tribes of Indians amongst whom I have travelled, I selected the Chinooks, one of the tribes most remote from this part of the continent, and whose manners and customs are so much at variance with our own, as to render some notice of them, from personal observation, probably both novel and interesting. Other communications of the incidents and results of my travels among the Indians of the North West, having since appeared in the Journal, I have revised my account of the Chinooks, with a view to its appearance, along with the notices of the Walla Wallas, and others of the Aborigines of this continent in the New Series.

The Flat-Head Indians are met with along the banks of the Columbia river from its mouth eastward to the Cascades, a distance of about 130 miles; they extend up the Walamett river south about 30 or 40 miles, and through the district lying between the Walamett and Fort Astoria, now called Fort George. To the north they extend along the Cowlitz river and the tract of land lying between that and Puget's Sound. About two-thirds of Vancouver's Island is also occupied by them, and they are found along the coasts of Puget's Sound and the Straits of Juan de Fuca. The Flat-Heads are divided into numerous tribes, each having its own peculiar locality, and differing more or less from the others in language, customs, and manners.

Of these I have selected, as the subject of the present paper, the Chinooks, a tribe inhabiting the tract of country at the mouth of the Columbia river. Residing among the Flat-Heads, I remained from the fall of 1846 to the following autumn of 1847, and had consequently ample opportunity of becoming acquainted with the peculiar habits and customs of the tribe. They are governed by a Chief called This name has no translation: the Indians on the west Casenov. side of the Rocky Mountains differing from those on the east, in having hereditary names, to which no particuliar meaning appears to be attached, and the derivation of which is in many instances forgotten. Casenov is a man of advanced age, and resides principally at Fort Vancouver, about 90 miles from the mouth of the Columbia. I made a sketch of him while staying there, and obtained the following information as to his history :-- Previous to 1829 Casenov was considered a great warrior, and could lead into the field 1,000 men, but in that year the Hudson's Bay Company and emigrants from the United States introduced the plough for the first time into Oregon, and the locality, hitherto considered one of the most healthy, was almost depopulated by the fever and ague.

Chinook Point, the principal settlement of the tribe, at the mouth of the river, where King Cumcomley ruled in 1811, was nearly reduced to one-half its numbers. The Klatsup village now contains but a small remnant of its former inhabitants. Wasiackum, Catlamet, Kullowith, the settlements at the mouth of the Cowlitz, Kallemo, Kattlepootle and Walkumup are entirely extinct as villages. On Sovey's Island there were formerly four villages but now there scarcely remains a lodge. They died of this disease in such numbers that their bodies lay unburied on the river's banks, and many were to be met with floating down the stream. The Hudson's Bay Company supplied them liberally with Quinine and other medicines, but the good effects of these were almost entirely counteracted by their mode of living and obstinacy in persisting in their own peculiar mode of treatment, which consisted principally in plunging into the river without reference to the particular crisis of the disease.

From these causes the numbers of the Indians have been very much reduced, and the effective power of the tribes so greatly diminished that the influence which Casenov owed to the number of his followers has correspondingly declined; his own immediate family consisting of ten wives, four children, and eighteen slaves, being reduced in one year to one wife, one child, and two slaves. Their decrease since that time has also been fearfully accelerated by the introduction of ardent spirits, which, in spite of prohibition and fines against selling it to Indians, they manage to obtain from their vicinity to Oregon city, where whiskey, or a poisonous compound called there *blue ruin*, is illicitly distilled. I have scarcely ever met with an Indian in that vicinity who would not get drunk if he could procure the means, and it is a matter of astonishment how very small a quantity suffices to intoxicate these unfortunate beings, although they always dilute it largely in order to prolong the pleasure they derive from drinking.

Casenov is a man of more than ordinary talent for an Indian, and he has maintained his great influence over his tribe chiefly by means of the superstitious dread in which they hold him. This influence was wielded with unflinching severity towards them, although he has ever proved himself the firm friend of the white man. For many years, in the early period of his life, he kept a hired assassin to remove any obnoxious individual against whom he entertained personal enmity. This brave, whose occupation was no secret, went by the name of Casenov's Sköcoom or evil genius. He finally fell in love with one of Casenov's wives who eloped with him. Casenov vowed vengeance, but the pair for a long time eluded his search, until one day he met her in a canoe near the mouth of the Cowlitz river and shot her on the spot. After this he lived in such continual dread of the lover's vengeance that for nearly a year he never ventured to sleep, but in the midst of a body guard of forty armed warriors, until at last he succeeded in tracing his foe out, and had him assassinated by the man who had succeeded him in his old office.

The Chinooks over whom Casenov presides carry the process of flattening the head to a greater extent than any other of the Flat-Head tribes. The process is as follows :-- The Indian mothers all carry their infants strapped to a piece of board covered with moss or loose fibres of cedar bark, and in order to flatten the head they place a pad on the forehead of the child, on the top of which is laid a piece of smooth bark bound on by a leathern band passing through holes in the board on either side and kept tightly pressed across the front of the head. A sort of pillow of grass or cedar fibres is placed under the back of the neck to support it.

This process commences with the birth of the infant, and is continned for a period of from eight to twelve months, by which time the head has lost its natural shape and acquired that of a wedge, the front of the skull becoming flat, broad, and higher at the crown, giving it a most unnatural appearance.

It might be presumed that from the extent to which this is

carried the operation must be attended with great suffering to the infant, but I never heard the infants crying or moaning, although I have seen their eyes seemingly starting out of the sockets from the great pressure. But on the contrary, when the bandages were removed I have noticed them cry until they were replaced.

From the apparent dullness of the children whilst under the pressure I should imagine that a state of torpor or insensibility is induced, and that a return to consciousness occasioned by its removal must be naturally followed by the sense of pain.

This unnatural operation does not however seem to injure the health, the mortality amongst the Flat-Head children not being perceptibly greater than amongst other Indian tribes. Nor does it seem to injure their intellect; on the contrary, the Flat-Heads are generally considered fully as intelligent as the surrounding tribes who allow their heads to preserve their natural shape; and it is from amongst the round-heads that the Flat-Heads take their slaves. They look with contempt even upon the whites for having round-heads, the *flat-head* being considered as the distinguishing mark of freedom. I may here remark, that, amongst the tribes who have slaves there is always something which conspicuously marks the difference between the slave and the free, such as the Chimseyan, who wear a ring in the nose, and the Babbenes who have a large piece of wood inserted through the under lip. The Chinooks, like all other Indian tribes, pluck out the beard on its first appearance.

I would give a specimen of the barbarous language of these people, were it not impossible to represent by any combination of the letters of our alphabet the horribly harsh, gasping, spluttering sounds which proceed from their throats, apparently unguided either by the tongue or lips. It is so difficult to acquire a mastery of their language that none have been able to attain it unless those who have been born amongst them. They have, however, by their intercourse with the English and French traders succeeded in amalgamating, after a fashion, some words of each of these tongues with their own, and have formed a sort of Patois, barbarous enough certainly, but still sufficient to enable them to communicate with the traders.

This Patois I succeeded, after some short time, in acquiring, and could converse with most of the chiefs with tolerable ease. Their common salutation is *Clah hoh ah yah*, originating, as I believe in their having heard in the early days of the fur trade a gentleman named Clark frequently addressed by his friends, "Clark, how are you?" This salutation is now applied to every white man, their own language affording no appropriate expression. Their language is also peculiar in containing no oaths, or any words expressive of gratitude or thanks.

Their habits are extremely filthy, their persons abounding with vermin, and one of their chief amusements consists in picking these disgusting insects from each others' heads and eating them. On my asking an Indian one day why he ate them, he replied that they bit him and he gratified his revenge by biting them in return. It may naturally be supposed that they are thus beset from want of combs or other means of displacing the intruders; but this is not the case, they pride themselves on carrying such companions about them, and giving their friends the opportunity of amusing themselves in hunting and eating them.

The costume of the men consists of a musk-rat skin robe, the size of one of our ordinary blankets, thrown over the shoulders, without any breech-cloth, moccassins or leggings. Painting the face is not much practised amongst them except on extraordinary occasions, such as the death of a relative, some solemn feast, or going on a war party. The female dress consists of a girdle of cedar bark round the waist, with a dense mass of strings of the same material hanging from it all around and reaching almost to the knees. This is their sole summer habiliment. They, however, in very severe weather add the muskrat blanket. They also make another description of blanket from the skin of the wild goose, which is here taken in great abundance. The skin is stripped from the bird with the feathers on, and cut into strips, which they twist so as to have the feathers outwards. This makes a feathered cord, and is then netted together so as to form a blanket, the feathers filling up the meshes, and rendering it a light and very warm covering. In the summer these are entirely thrown aside, not being in any case worn from feelings of delicacy, and the men go quite naked, though the women always wear the cedar petticoat.

The country which the Chinooks inhabit being almost destitute of furs they have little to trade in with the whites. This, coupled with their laziness—probably induced by the ease with which they procure fish, which is their chief subsistence—prevents their obtaining ornaments of European manufacture, consequently anything of the kind is seldom seen amongst them. They, however, wear long strings of small shells found on the coast called Ioquas, and used by them also as money.

A great traffic is carried on amongst all the tribes through the medium of these shells, which are found only at Cape Flattery, at the entrance to the Straits of De Fuca. They are fished up from the bottom of the sea, and are found an inch and a-half to two inches in length; they are white, slender, hollow, and tapering to a point, slightly curved, and about the size of the stem of an ordinary clay tobacco pipe. They are valuable in proportion to their length, and their value increases according to a fixed ratio, forty shells being the standard number required to extend a fathoms' length, which number is in that case equal in value to a beaver's skin, but if thirty-nine be found long enough to make the fathom it would be worth two beaver skins, if thirty-eight three skins, and so on, increasing one beaver skin for every shell less than the standard number.

The Chinooks evince very little taste in comparison with some of the tribes on the eastern side of the Rocky Mountains, in ornamenting either their persons or their warlike or domestic implements. The only utensils I saw at all creditable to their decorative skill were carved bowls and spoons of horn, and baskets made of roots and grass woven so closely as to serve all purposes of a pail in holding and carrying water. In these they even boil the salmon which constitute their principal food. This is done by immersing the fish in one of the baskets filled with water, into which they throw red hot stones until the fish is cooked, and I have seen fish dressed as expeditiously by them in this way as if done in a kettle over a fire by our own people.

The salmon is taken during the months of June and July in immense numbers in the Columbia river and its tributaries by spearing and with gill nets. They have also a small hand net something like our common landing net, which is used in rapids where the salmon are crowded together and near the surface. These nets are ingeniously contrived, so that when a fish is in them his own struggles loosen a little stick which keeps the mouth of the net open while empty, but which, when the net is full, immediately draws it together like a purse with the weight of the salmon and effectually secures the prey.

The salmon taken during this period of the year are split open and dried in the sun for their winter's supply. I have never seen salt made use of by any tribe of Indians for the purpose of preserving food, and they all evince the greatest dislike to salt meat.

I may here mention a curious fact respecting the salmon of the Columbia river; they have never been known to rise to a fly, although it has been frequently tried by gentlemen of the Hudson's Bay Company, with the very best tackle. The salmon go up the river as far as they possibly can and into all its tributary streams in myriads; it is, however, a well known fact that after spawning they never return to the sea, but all die in the river; the Columbia is hardly ever free from gill nets, and no salmon has ever been taken returning; and in the fall, wherever still water occurs, the whole place is tainted by their putrid bodies floating in immense masses. I have been obliged to travel through a whole night trying to find an encampment free from their disgusting effluvia.

The Chinooks also catch a considerable number of sturgeon, which here attain to an enormous size, weighing from four to six cwt.; this is done by means of a long-jointed spear handle seventy or eighty feet in length, fitted into, but not actually fastened to a barbed spearhead, to which is attached a line, with this they feel along the bottom of the river, where the sturgeon are found lying at the spawning season. Upon feeling the fish the barbed spear is driven in and the handle withdrawn. The fish is then gradually drawn in by the line, which being very long allows the sturgeon room to waste his great strength, so that he can with safety be taken into the canoe or towed ashore.

At the mouth of the river a very small fish, about the size of our Sardine, is caught in immense numbers. It is called there Uhlékun, and is much prized on account of its delicacy and extraordinary fatness. When dried this fish will burn from one end to the other with a clear steady light like a candle. The Uhlékuns are caught with astonishing rapidity by means of an instrument about seven feet long; the handle is about three feet, into which is fixed a curved wooden blade about four feet, somewhat the shape of a sabre, with the edge at the back. 'In this edge, at the distance of an inch and a-half, are inserted sharp bone teeth about an inch long. The Indian standing in the canoe draws this edgeways with both hands, holding it like a paddle, rapidly through the dense shoals of fish which are so thick that almost every tooth will strike a fish. One knock across the thwarts safely deposits them in the bottom of the canoe. This is done with such rapidity that the Indians will not use nets for this description of fishing.

There are few whales now caught on the coast, but the Indians are most enthusiastic in the chase. Upon a whale being seen blowing in the offing they rush down to their large cances and push off, with ten or twelve men in each. The cances are furnished with a number of strong seal skin bags filled with air, and made with great care and skill, capable of containing about ten gallons. To each bag is attached a barbed spear-head by a strong string about eight or nine feet long, and in the socket of the spear-head is fitted a handle five or

Vol. II-B

six feet in length. Upon coming up with the whale, the barbed heads, with the bags attached, are driven into it and the handles withdrawn. The attack is continually renewed until the whale is no lenger able to sink from the buoyancy of the bags, when he is despatched and towed ashore. The blubber of the whale is much prized amongst them, and is cut into strips about two feet long and four inches wide, and eaten generally with their dried fish.

Clams and oysters are very abundant, and seals, wild ducks and geees, are taken in great plenty, but their fishing is so productive that the Indians subsist with little labour. They are also very fond of herrings' roe, which they collect in the following manner :—They sink cedar branches to the bottom of the river, in shallow places, by placing upon them a few heavy stones, taking care not to cover the green foliage, as the fish prefer spawning on anything green, and they literally cover all the branches by next morning with spawn. The Indians wash this off in their water-proof baskets, to the bottom of which the roe sinks ; this is squeezed by the hands into little balls and then dried, and is very palatable.

The only vegetables in use amongst the Chinooks are the Camas and Wappattoo. The Camas is a bulbous root much resembling the onion in outward appearance but is more like the potato when cooked and is very good eating. The Wappattoo is somewhat similar but larger and not so dry or delicate in its flavour. They are found in immense quantities in the plains in the vicinity of Fort Vancouver, and in the spring of the year present a most curious and beautiful appearance, the whole surface presenting an uninterrupted sheet of bright ultramarine blue from the innumerable blossoms of these plants. They are cooked by digging a hole in the ground, then putting down a layer of hot stones, covering them with dry grass, on which the roots are placed; they are then covered with a layer of grass, and on the top of this they place earth, with a small hole perforated through the earth and grass down to the vegetables. Into this they pour water, which, reaching the hot stones, forms sufficient steam to completely cook the roots in a short time, the hole being immediately stopped up after the introduction of the water. They often adopt the same ingenious process for cooking fish, meat, and game.

There is another article of food made use of amongst them, which from its disgusting nature I should have been tempted to omit, were it not a peculiarily characteristic trait of the Chinook Indian, both from its extraordinary character, and its use being confined solely to this tribe; it is, however, regarded only as a luxury and not as a general article of food. The whites have given it the name of Chinook Olives, and it is prepared as follows :--About a bushel of acorns are placed in a hole dug for the purpose close to the entrance of the lodge or hut, and covered over with a thin layer of grass, on top of which is laid about half a foot of earth; every member of the family for the next five or six months regards this hole as the special place of deposit for urine, which is on no occasion to be diverted from its legitimate receptacle. Even should a member of the family be sick and unable to reach it for this purpose, the fluid is carefully collected and carried thither. However disgusting such an cdoriferous preparation would be to people in civilized life the product is regarded by them as the greatest of all delicacies; so great indeed is the fondness they evince for this horrid preparation that even when brought amongst civilized society they still yearn after it and will go any distance to obtain it. A gentleman in charge of Fort George had taken to himself a wife, a woman of this tribe, who of course partook with himself of the best food the Fort could furnish; notwithstanding which, when he returned home one day his nostrils where regaled with a stench so nauseating that he at once enquired where she had deposited the Chinook olives, as he knew that nothing else could poison the atmosphere in such a manner. Fearful of losing her dearly-prized luxury she strenuously denied their possession : his nose however, led him to the place of deposit, and they were speedily consigned to the river. His mortification was afterwards not a little increased by learning that she had purchased the delicacy with one of his best blankets.

During the season the Chinooks are gathering Camas and fishing, they live in lodges constructed by means of a few poles covered with mats made of rushes, which can be easily moved from place to place; but in the villages they build permanent huts of split cedar boards. Having selected a dry place for the village, a hole is dug about three feet deep and about twenty feet square : round the sides of this, square cedar boards are sunk and fastened together with cords and twisted roots, rising about four feet above the outer level ; two posts are sunk at the middle of each end with a crutch at top, on which the ridge pole rests, and boards are laid from thence to the top of the upright boards. Fastened in the same manner round the interior are erected sleeping places, one above another, something like the berths in a vessel, but larger. In the centre the fire is made, the smoke of which escapes by means of a hole left in the roof for that purpose. These lodges are filthy beyond description and swarm with vermin. The fire is procured by means of a flat piece of dry cedar, in which a small hol.

low is cut, with a channel for the ignited charcoal to run over; this piece the Indian sits on, to hold it steady, while he rapidly twirls a round stick of the same wood between the palms of his hands with the point pressed into the hollow of the flat piece. In a very short time sparks begin to fall through the channel upon finely frayed cedar bark placed underneath, which they soon ignite. There is a great deal of knack in doing this, but those who are used to it will light a fire in a very short time. The men usually carry these sticks about with them, as after they have been once used they produce the fire quicker.

The only warlike implements I have seen amongst the Chinooks were bows and arrows. The bows are made from the Yew tree, and the arrows are feathered and pointed with sharp bone. These they use with great precision.

Their canoes are hollowed out of the cedar, and some of them are very large, as this tree grows to an immense size in the neighbourhood. They make them exceedingly light, and from their formation they are capable of withstanding very heavy seas.

Slavery is carried on to a great extent along the North-West coast and in Vancouver's Island; and the Chinooks, considering how much they themselves have been reduced in numbers, still retain a large number of slaves. These are usually procured from the Chastay tribe who live near the Umqua, a river south of the Columbia emptying into the Pacific. They are sometimes seized by war parties, but are often bought from their own people. They do not flatten the head. nor is the child of one of them (although by a Chinook father,) allowed this distinguishing mark of freedom. Their slavery is of the most abject description : the Chinook men and women treat them with great severity, and exercise the power of life and death at pleasure. An instance of the manner in which the Chastay slaves are treated presented itself to my own observation one morning while I was out sketching on Vancouver's Island. I saw upon the rocks the dead body of a young woman whom I had seen a few days previously walking about in perfect health, thrown out to the vultures and crows. I mentioned it to a gentleman of the Hudson's Bay Company, who accompanied me to the lodge she belonged to, where we found an Indian woman, her mistress, who made light of her death, and who was no doubt the cause of it. She said a slave had no right to burial. She was furious on being told that the slave was as good as herself. "She, the daughter of a chief, no better than a slave !" She then stalked out of the lodge with great dignity; the next morning she had taken

down the lodge and was gone. I was also told by an eye witness, of a chief who, having erected a colossal idol of wood, sacrificed five slaves to it, barbarously murdering them at its base, and asking in a boasting tone who among them could afford to kill so many slaves. One of these slaves was a handsome girl who had lived from her infancy in his family, and begging most piteously for life, reminded him of the care she had taken of his children and all the services she had rendered; but her pleadings were of no avail, and the brutal wretch with his own hand plunged a knife four times into her body before she ceased her appeals for mercy. The only distinction made in her favour was that she was buried, instead of being, like her miserable companions, thrown out on the beach.

The principal amusement of the Chinooks is gambling, which is carried to great excess amongst them. You never visit the camp but you hear the monotonous gambling song of " he ha, ha," accompanied by the beating of small sticks on some hollow substance. Their games do not exceed two or three, and are of a simple nature. The one most generally played consists in holding in each hand a small piece of stick the thickness of a goose quill and about an inch and a-half in length, one plain and the other distinguished by a little thread wound round it, the opposite party being required to guess in which hand the marked stick is to be found. A Chinook will play at this simple game for days and nights together, uptil he has gambled away everything he possesses, even his wife. They play, however, with much equanimity, and I never saw any ill-feeling evinced by the loser against his successful opponent. They will cheat if they can, and pride themselves on its success ; if detected no unpleasant consequence follows, the offending party being merely laughed at and allowed to amend his play.

Another game to which the Chinooks are very partial is played by two or three on each side. The rivals sit on the ground opposite each other with the stakes lying in the centre, one begins with his hands on the ground in which he holds four small sticks covered from sight by a mat, these he arranges in any one of a certain number of forms prescribed by the rules of the game, and his opponent on the opposite side endeavours to guess which form he has chosen; if successful a mark is stuck up in his favour, and the sticks are handed to the next, if not the player counts and still goes on till discovered. When those on one side have gone through, the others commence. At the conclusion the marks are counted and the holder of the greater number wins. This game is also accompanied by singing, in which all the bystanders join.

Another game which I have seen amongst them is called Al-kolloch, and is one that is universal along the Columbia river. It is considered the most interesting and important as it requires great skill. A smooth level piece of ground is chosen, and a slight barrier of a couple of sticks laid lengthways is made at each end. These are forty or fifty feet apart and a few inches high. The two opponents, stripped naked, are armed each with a very slight spear about three feet long and finely pointed with bone. One of them takes a ring made of bone or some heavy wood, about three inches in diameter, and wound round with cord, on the inner circumference of which are fastened six beads of different colours at equal distances, to each of which a separate numerical value is attached; the ring is then rolled along the ground to one of the barriers and is followed at the distance of two or three yards by the players, and as the ring strikes the barrier and is falling on its side the spears are thrown so that the ring may fall on them; if only one of the spears should be covered by the ring the owner of it counts according to the coloured bead over it. But it generally happens, from the dexterity of the players, that the ring covers both spears, and each count according to the colours of the beads above his weapon. They then play towards the other barrier, and so on until one party has attained the number agreed upon for game.

The Chinooks have tolerably good horses, and are fond of racing, at which they bet considerably; they are expert jockeys and ride fearlessly. They also take great delight in a game with a ball, which is played by them in the same manner as by the Cree, Chippewa, and Sioux Indians. Two poles are erected about a mile apart, and the company is divided into two bands armed with sticks, having a small ring or hoop at the end, with which the ball is picked up and thrown to a great distance, each party then strives to get the ball past their own goal. There are sometimes hundreds on a side, and the play is kept up with great noise and excitement. At this game they also bet heavily, as it is generally played between tribes or villages.

The sepulchral rites of this singular tribe of Indians are too curious to be entirely omitted. Upon the death of a Chinook the body is securely tied up in rush matting and placed in the best canoe they can procure, without any peculiar ceremonies. This canoe is as highly decorated as the family of the deceased can afford. Tin cups, kettles, plates, pieces of cotton, red cloth, and furs, and in fact everything which they themselves most value, and which are most difficult for them to obtain, are hung round the canoe ; inside, beside the body they place paddles, spears, bows and arrows, and food, with everything else which they consider necessary for a very long journey. I have even found beads, Ioquas shells, brass buttons, and small coins in the mouths of the skeletons. The canoe is then taken to the bur ial place of the tribe, generally selected for its isolated situation. The two principal places are rocky islands in the lower part of the Columbia River. One is called Coffin Rock from the appearance it presents, covered with the raised biers of the deceased members of the tribe. To these they tow the canoe, which is then either fastened up in a tree or supported on a sort of frame four or five feet from the ground made of strong cedar boards, and holes bored in the bottom of the canoe to let the water run out; it is then covered with a large piece of bark to protect it from the rain. Before leaving, the usefulness of every article left with the corpse is destroyed, by making holes in the kettles, cans, and baskets, cracking the bows, arrows, and spears, and if there is a gun they take the lock off, believing that the Great Spirit will mend them upon the deceased arriving at the hunting grounds of their Elysium. The greatest crime which an Indian can commit in the eyes of his people is that of desecrating one of these canoes, and it very seldom happens that the slightest thing is removed.

In obtaining a specimen of one of the peculiarly formed skulls of the tribe I had to use the greatest precaution, and ran no small risk not only in getting it, but in having it in my possession afterwards. Even the voyageurs would have refused to travel with me had they known that I had it among my collections, not only on account of the superstitous dread in which they hold these burial places, but also on account of the danger arising from a discovery, which might have cost the lives of the whole party.

A few years before my arrival at Fort Vancouver, Mr. Douglass, who was then in charge, heard from his office in the Fort the report of a gun inside the gates; this being a breach of discipline he hurried out to enquire the cause of so unusual a circumstance, and found one of Casenov's slaves standing over the body of an Indian whom he had just killed, and in the act of reloading his gun with apparent indifference, Casenov himself standing by. On Mr. Douglass arriving at the spot, he was told by Casenov, with an apology, that the man deserved death according to the laws of the tribe, who, as well as the white man inflicted punishment proportionate to the nature of the offence. In this case the crime was one of the greatest an Indian could be guilty of, namely, the robbing the sepulchre canoes. Mr. Douglass after severely reprimanding him allowed him to depart with the dead body.

Sacred as the Indians hold their burial places, Casenov himself, a short time after the latter occurrence, had his only son buried in the cemetery of the fort. He died of consumption-a disease very frequent amongst all Indians-proceeding no doubt from their constant exposure to the sudden vicissitudes of the climate. The coffin was made sufficiently large to contain all the necessaries supposed to be required for his comfort and convenience in the world of spirits. The chaplain of the fort read the usual service at the grave, and after the conclusion of the ceremony, Casenov returned to his lodge, and the same evening attempted, as narrated below, the life of the bereaved mother, who was the daughter of the great chief generally known as King Comcomly, so beautifully alluded to in Washington Irving's "Astoria." She was formerly the wife of a Mr. McDougall, who bought her from her father for, as it was supposed, the enormous price of ten articles of each description, guns, blankets, knives, hatchets, &c., then in Fort Astoria. Comcomly, however, acted with unexpected liberality on the occasion by carpeting her path from the canoe to the Fort with sea otter skins, at that time numerous and valuable, but now scarce, and presenting them as a dowry, in reality far exceeding in value the articles at which she had been estimated. On Mr. McDougall's leaving the Indian country she became the wife of Casenov.

It is the prevailing opinion of the chiefs that they and their sons are too important to die in a natural way, and whenever the event takes place they attribute it to the malevolent influence of some other person, whom they fix upon, often in the most unaccountable manner, frequently selecting those the most dear to themselves and the deceased. The person so selected is sacrificed without hesitation. On this occasion Casenov selected the afflicted mother, notwithstanding she had during the sickness of her son been most assiduous and devoted in her attentions to him, and of Casenov's several wives she was the one he most loved ; but it is the general belief of the Indians on the west side of the mountains, that the severer the privation they inflict upon themselves the greater is therefore the manifestation of their grief, and the more pleasing to the departed spirit. Casenov assigned to me, as an additional motive for his wish to kill his wife, that as he knew she had been so useful to her son and so necessary to his happiness and comfort in this world, he wished to send her with him as his companion on his long journey. She, however, escaped into the woods, and next morning reached the Fort, imploring protection; she was accordingly secreted for several days until her own relations took her home to Chinook Point. In the meantime a woman was found murdered in the woods and the act was universally attributed to Casenov or one of his emissaries.

I may here mention a painful occurence which took place on Thompson's River, in New Caledonia, in further illustration of this peculiar superstition. A Chief dying, his widow considered a sacrifice as indispensable, but having selected a victim of rather too much importance, she was unable for some time to accomplish her object ; at length the nephew of the chief, no longer able to bear the continual taunts of cowardice which she unceasingly heaped upon him, seized his gun and started for the Company's Fort on the river, about twenty miles distant. On arriving, he was courteously received by Mr. Black, the gentleman in charge of the Fort, who expressed great regret at the death of his old friend the chief. After presenting the Indian with something to eat, and giving him some tobacco, Mr. Black turned to leave the room, and while opening the door was shot from behind by his treacherous guest and immediately expired. The murderer succeeded in escaping from the Fort, but the tribe, who were warmly attached to Mr. Black, took his revenge upon themselves and hunted him down. This was done more to evince their high esteem for Mr. Black than from any sense of impropriety in the customary sacrifice.

I never heard any traditions amongst the Chinooks as to their former origin, although such traditions are common among the Indian tribes on the east side of the Rocky mountains. They do not believe in any future state of punishment, although in this world they suppose themselves exposed to the malicious designs of the Sköcoom or evil genius, to whom they attribute all their misfortunes and ill luck. The good spirit is called the *Hias Soch-a-li Ti-yah*, that is the Great High Chief from whom they obtain all that is good in this life, and to whose happy and peaceful hunting grounds they believe they shall all eventually go, to reside for ever in comfort and abundance.

The medicine men of the tribe are supposed to possess a mysterious influence with these two spirits, either for good or evil, and of course possess great power in the tribe. These medicine men form a secret society, the initiation into which is accompanied with great coremony and much expense. I witnessed, whilst amongst them, the initiation of a canditate, which was as follows :---The canditate has to

prepare a feast for his friends and all who choose to partake of it, and make presents to the other medicine men. A lodge is prepared for him, which he enters, and remains alone for three days and nights. without food, whilst those already initiated keep dancing and singing round the lodge during the whole time. After this fast which is supposed to endue him with wonderful skill, he is taken up apparently lifeless and plunged into the nearest cold water, where they rub and wash him until he revives. This they call "washing the dead." As soon as he revives he runs into the woods, and soon returns dressed as a medicine man, in a costume which generally consists of the light down of the goose stuck all over the body and head with thick grease, and a mantle of friezed cedar bark. With the medicine rattle in his hand he now collects all his property, blankets, shells and ornaments, and distributes the whole amongst his friends, trusting for his future support to the fees of his profession. The dancing and singing are still continued with great vigour during the division of the property, at the conclusion of which the whole party again sit down to feast, apparently with miraculous appetites, the quantity of food consumed being perfectly incredible.

I witnessed one day their mode of treatment of the sick whilst passing through a village. Hearing a horrible noise in one of the lodges, I entered it, and found an old woman supporting one of the handsomest girls of the tribe I had ever seen; cross-legged and naked in the middle of the room sat the medicine man with a wooden dish full of water before him, and twelve or fifteen other men sitting round the lodge. The object in view was to cure the girl of a disease affecting her side. As soon as my presence was noticed a space was cleared for me to sit down. The officiating medicine man appeared in a state of profuse pespiration from the exertions he had used, and soon took his seat amongst the rest as if quite exhausted ; a younger medicine man then took his place in front of the bowl and close beside the patient; throwing off his blanket he commenced singing and gesticulating in the most violent manner. whilst the others kept time by beating with little sticks on hollow wooden bowls and drums, singing continually. After exercising himself in this manner for about half an hour, until the pespiration ran in streams down his body, he darted suddenly upon the young woman catching hold of her side with his teeth and shaking her for a few minutes, as one dog does another in fighting. The patient sceming to suffer great agony. He then relinquished his hold, and cried out he had got it, at the some time holding his hands to his mouth, after which he plunged

them in the water, and pretended to hold down with great difficulty the disease which he had extracted lest it might spring out and return to its victim. At length having obtained the mastery over it, turning himself round to me in an exulting manner, he held something up between the finger and thumb of each hand, which had the appearance of a piece of cartilage, whereupon one of the Indians sharpened his knife and divided it in two, leaving one end in each hand. One of the pieces he threw into the water and the other into the fire, accompanying the action with a diabolical noise which none but a medicine man can make; after which he got up perfectly well satisfied with himself, although the poor patient scemed to me anything but relieved by the violent treatment she had undergone.

My principal object in travelling among the Indian tribes of the Far West was to obtain accurate sketches of their Chiefs, medicine men, &c., and representations of their most characteristic manners and customs, but it was only by great persuasion that I could induce the Indians to allow me to take their portraits. They had an undefined superstitious dread of losing something by the process, as though in taking their likeness something pertaining to themselves was carried off. The women, moreover, had the idea that the possessor of their picture would hold an unlimited influence over them. In one case I had taken the likeness of a woman at the Cowlitz river, and on my return about three months afterwards, I called at the lodge of Kisscox, the chief of the tribe, where I had been in the habit of visiting frequently, and had always been received with great kindness, but on this occasion I found him and his family unusually distant in their manner, and the children even running away from me and hiding; at last he asked me if I had not taken the likeness of a woman when last amongst them, I said I had, and mentioned her name, "Cawitchum," a dead silence ensued, nor could I get the slightest answer to my enquiries. Upon leaving the lodge I met a half-breed, who told me that Cawitchum was dead, and that I was supposed to be the cause of her death. The silence was occasioned by my having mentioned a dead person's name, which is considered disrespectful to the deceased, and unlucky. I immediatly left the neighbourhood, well knowing the danger that would result from my meeting with any of her relations.

Upon trying to persuade another Indian to sit for his likeness he asked me repeatedly if it would not endanger his life. Being very much in want of tobacco he at length appeared convinced by my assurances that it could do him no harm, but when the picture was finished he held up the tobacco and said it was a small piece to risk his life for. I asked another Indian while he was sitting in his lodge surrounded by his eight wives, for the same favor, but the ladies all commenced violently jabbering at me until I was glad to get off: he apparently was much gratified at the interest which his wives took in his welfare. I however met him alone some short time afterwards and got him to consent, with my usual bribe, a piece of tobacco. I could relate numerous instances of this superstitious dread of portrait painting, but the foregoing sufficiently illustrates the general feeling on the subject.

I shall conclude this paper by relating a legend told me by an old Indian while paddling in a canoe past an isolated rock on the shores of the Pacific, as it gives an idea of the general character of the legends on the coast, which are however very few, and generally told in an unconnected and confused manner. The rock with which the following Indian legend is associated, rises to a height of between six and seven feet above the water, and measures little more than four feet in circumference. I could not observe any very special peculiarity in the formation of this rock while paddling past it in a canoe; and, at least from the points of observation presented to my eye, no resemblance to the human figure-such as the conclusion of the legend might lead us to anticipate,-appeared to be traceable. Standing, however, as this rock does, entirely isolated, and without any other visible for miles around, it has naturally become an object of special note to the Indians, and is not uncalculated, from its solitary position, to be made the scene of some of the fanciful creations of their superstitous credulity.

"It is many moons since a Nasquawley family lived near this spot. It consisted of a widow with four sons; one of them was by her first husband, the other three by her second. The three younger sons treated their elder brother with great unkindness, refusing him any share of the produce of their hunting and fishing; he, on the contrary, wishing to conciliate them, always gave them a share of his spoils. He in fact was a great medicine man, although this was unknown to them, and being tired of their harsh treatment, which no kindness on his part seemed to soften, he at length resolved to retaliate. He accordingly one day entered the lodge where they were feasting and told them that there was a large seal a short distance off. They instantly seized their spears and started in the direction he pointed out, and coming up to the animal the cldest drove his spear into it. This seal was 'a great medicine,' a familiar of the

elder brother who had himself created it for the occasion. The foremost of them had no sooner driven in his spear than he found it impossible to disengage his hand from the handle or to draw it out; the two others drove in their spears and with the like effect. The seal now took to the water, dragging them after it, and swam far out to sea. Having travelled on for many miles they saw an island in the distance, towards which the seal made ; on nearing the shore they found that they could, for the first time, remove their hands from their spears; they accordingly landed, and supposing themselves in some enemies' country, they hid themselves in a clump of bushes from While lying concealed they saw a diminutive canoe observation. coming round a point in the distance, paddled by a very little man. who, when he came opposite to where they were, anchored his boat with a stone attached to a long line, without perceiving them. He now sprang over the side, and diving down, remained a long time under water, at length he rose to the surface and brought with him a large fish, which he threw into the boat; this he repeated several times, each time looking in to count the fish he had caught. The three brothers being very hungry, one of them offered to swim out while the little man was under water and steal one of the fish; this he safely accomplished before the return of the fisherman, but the little fellow no sooner returned with another fish than he discovered that one of those already caught was missing, and stretching out his hand he passed it slowly along the horizon, until it pointed directly to their place of concealment. He now drew up his anchor and paddled to the shore, and immediately discovered the three brothers ; and being as miraculously strong as he was diminutive, he tied their hands and feet together and throwing them into his cance. jumped in and paddled back in the direction from whence he had come. Having rounded the distant point where they first descried him, they came to a village inhabited by a race of people as small as their captor, their houses, boats, and utensils being all in proportion to themselves. The three brothers were taken out and thrown bound as they were into a lodge, while a council was convened to decide upon their fate. During the sitting of the council an immense flock of birds resembling geese, but much larger, pounced down upon the inhabitants and commenced a violent attack. These birds had the power of throwing their sharp quills like the porcupine, and though the little warriors fought with great valour they soon became covered with the piercing darts, and all sunk insensible on the ground ; when all resistance had ceased the birds took to flight and disap-

peared. The three brothers had witnessed the conflict from their place of confinement, and with much labour had succeeded in releasing themselves from their bonds, when they went to the battle ground and commenced pulling the quills from the apparently lifeless bodies, but no sooner had they done this than all instantly returned to consciousness. When all of them had become well again they wished to express their gratitude to their preservers and they offered to grant whatsoever they should desire. The three brothers therefore requested to be sent back to their own country. A council was accordingly called to decide upon the easiest mode of doing so, and they eventually determined upon employing a whale for the purpose. The three brothers were then seated upon the back of the monster and proceeded in the direction of Nasquawley : however, when they had reached about half way the whale began to think what a fool he was for carrying them instead of turning them into porpoises and letting them swim home themselves. Now the whale being a "Soch-a-li-Tivah" or great spirit-that is the highest of all animal spirits-but of course inferior to the "Hias Soch-a-li Tiyah," who is the Great Spirit over all things, was able to do this at will, and he accordingly turned the three brothers into porpoises. This therefore is the way that the porpoises first came into existence, and accounts for their being constantly at war with the seals, one of which species was the cause of their first misfortunes. After the three brothers had so strangely disappeared their mother came down to the beach and remained there for days watching for their return and bewailing their absence with tears. While thus engaged one day the whale happened to pass by and taking pity on her distress he turned her into that stone."

# NOTE ON THE OXALATE OF MANGANESE.

BY HENRY OROFT, D.C.L., F.C.S., PROFESSOR OF CHEMISTRY, UNIVERSITY COLLEGE, TORONTO.

Read before the Canadian Institute, December 20th, 1856.

In Gmelin's Handbuch, Vol. IV., the oxalate of the protoxide of manganese is described as having been obtained by Graham, combined with 5 equivalents (24, 16 per cent.) of water, by precipitation

30
of a solution of one part of manganese-salt in 100 of water, by means of oxalate of potassa; and this compound is stated to lose no water at 212°.F. Nothing is said with regard to the amount of water in the precipitate obtained from concentrated manganese solutions by oxalic acid.

There is evidently some error in the above statement, for the formula MnO,  $C^2O^8+5$  HO requires 38,60 per cent. of water, and Mn O,  $C^2O^3+3$  HO requires 27.39.

In the 89th volume of the Annalen der Chemie and Pharmacie, Hausmann and Löwenthal give an analysis of the oxalate obtained by acting on freshly precipitated carbonate of manganese with oxalic acid, from which they deduce the formula Mn O,  $C^2O^3+2$  HO, for the salt dried at 212°. F.

The following experiments were made for the purpose of explaining the discrepancy.

Strong solutions of sulphate of manganese were precipitated by saturated solutions of oxalic acid, a granular white precipitate was obtained in both cases, which did not lose water at 212°. F. I. and II.

Similar solutions were mixed when boiling. III.

Sulphate of manganese was dissolved in 30 parts of water, and oxalic acid added, a light pinkish crystalline precipitate was formed after a time, which, in the course of a few days, changed into a perfectly white granular powder. IV.

Sulphate of manganese was dissolved in 30 parts of water, and a solution of oxalate of potassa added, a light pinkish crystalline precipitate gradually formed, having the appearance and lightness of benzoic acid, it absorbed and retained water like a sponge, and remained unchanged in the air at ordinary temperatures, but became perfectly white at 212°. F. V.

Sulphate of manganese was dissolved in 100 parts of water, and oxalate of potassa added; the same pink salt was obtained. VI. This should be the compound described by Graham, with 5 HO.

## WHITE SALT.

| V.  | 1.0575 | grms. | gave | 0.418 | ${\rm Mn^3O^4}$ | = 36.77 | per cent. | MnO |
|     | 1.3700 | 66    | 66   | 0.536 | "               | = 36.79 | 66        | 66  |
| VI. | 1.4395 | ٤,    | 66   | 0.567 | 66              | = 36.64 | "         | 66  |
|     | 1.5300 | 66    | 66   | 0.597 | 66              | = 36,39 | "         | 66  |
|     |        |       |      |       |                 |         |           |     |
|     |        |       |      |       | Moon            | 36.62   |           |     |

1.5300 heated to  $212^{\circ}$ .F. lost 0.134 HO = 8.75 per cent. HO, and became perfectly white.

The formula MnO,  $C^2O^3+3$  HO requires 36.09 per cent. MnO and one equivalent of water would = 9.09 per cent.

The red oxide of manganese is obtained by heating this salt, in a crystalline form; the complete conversion of the protoxide into the red oxide is only effected after a rather long roasting.

Burin du Buisson is of opinion that pure salts of the protoxide of manganese are colourless when in an anhydrous state, but reddish when hydrated, while Reithner and others ascribe the red colour to the presence of a salt of the sesquioxide. The pink colour of the above hydrate can scarcely be owing to the latter cause, inasmuch as the salt is produced both by oxalic acid and by oxalate of potash; and the salt with 2 HO is generally obtained perfectly white. (This salt is described by Liebig as having a tinge of pink, but in my experiments it was always white.) The pink crystallized salt changes in a warm atmosphere, even when kept in a close vessel, into the white compound, evolving water.

The oxalate dissolves readily in a hot solution of oxalate of ammonia, and crystalline compounds can be obtained as already described by Winkelblech: these crystalline crusts, however, seem to vary much in their composition, and are probably combinations of the true double salt with variable proportions of oxalate of ammonia, similar to the magnesia compounds lately described by Souchay and Leussen.

# REVIEWS.

Canada at the Universal Exhibition of 1855.—Printed by order of the Legislative Assembly. Toronto: John Lovell, 1856.

The success which attended the Canadian exhibition at London, in 1851, naturally led to the expectation that no efforts would be spared to present at Paris, in 1855, a correct representation of the Natural Productions and Industry of this vast Province.

32

It was a triumph of no common order to receive a public acknowledgement of "the superiority of the Canadian collection at London, as far as the mineral kingdom was concerned, to all countries that forwarded their products to the Exhibition," and the "very remarkable specimens of the chief varieties of Canadian timber," together "with the fine supply of wheats, every sample of more than average excellence." so favorably noticed by the jurors, inspired the hope that Canada would be fairly represented and appreciated at the great Paris Exhibition, in 1855. Nor has this hope been disappointed, when the vast distance which separated us from the scene of rivalry and display is considered, and the facilities which wealth, leisure, and position, conferred on the majority of European Exhibitors.

With few exceptions, it could scarcely be a subject of personal pecuniary interest to the farmers and manufacturers of this country to send the results of their industry or skill to compete with ages of experience in Europe. Even the products of our forests, though if known in all their variety and excellence beyond our borders, they would doubtless create a profitable market, yet, if their representation had been altogether left to the unremunerated zeal of private contributors, it is scarcely probable that even they would have been fairly represented. Hence the Provincial Committee, appointed to secure a fitting representation of the products of this Country at the Paris Exhibition, arrived at the conclusion, that any attempt to induce voluntary efforts by local fairs, such as those which were held at Toronto and Montreal previous to the Exhibition of 1851, would be fruitless, and that it would be absolutely necessary that the Provincial Committee should have the authority to purchase such articles as they deemed it expedient to transmit to Paris.

In accordance with this suggestion the Canadian Government appropriated a sufficient sum to cover all the expenses of the transit and ultimate purchase of the articles sent. It was further suggested by the Executive Committee that every effort should be made to secure a satisfactory representation of the great staple products of Canada-Minerals, Agricultural Products, and Timber—so successfully represented at London in 1851; and also, that the manufactures of the country should be exhibited in their progressive stages up to the highest point of perfection. Local exhibitions were held at Toronto and Montreal, and selections made as in 1851, for transmission to Paris. Hence it appears that no effort was spared to have Canada properly represented, and with what success we are informed by Mr. Taché's Report of "Canada at the Universal Exhibition of 1855."

VOL. II.-C.

# 34 REVIEWS-CANADA AT THE UNIVERSAL EXHIBITION.

We are told that the display of the products of Mines, Forests, and Agriculture "was truly magnificent," and that the premiums obtained were such as to give full satisfaction to all who were interested in exhibiting the natural resources of Canada to the greatest advantage. The samples of agricultural product were very fine, and included every variety of the cereals cultivated in this country. Fifty-six different kinds of minerals are enumerated in the catalogue of articles sent, and sixty-four kinds of woods, together with numerous models in wax of the vegetables and fruits grown in the Province. The Executive Council close their report, which forms the first part of Mr. Taché's volume, "with the consoling reflection that the most complete success has crowned the undertaking, for the due carrying out of which, the country has manifested such earnest solicitude."

The two special Commissioners, Sir W. Logan and Mr. Taché, divided the duties of their office, the former undertaking the arrangement of the exhibition; the latter, the diffusion of information respecting Canada throughout Europe, and of the entire exhibition throughout Canada. These efforts resulted in attracting a larger share of public attention to Canada, in proportion to its population, than to any other country; and, Count Jaubert, in his work entitled "La Botanique à l'exposition universelle de 1855," reproachfully says, "now we can form an estimate of the value of those few arpents of snow ceded to England with such culpable carelessness by the Government of Louis XV."

The testimony of many distinguished men may be adduced to shew that the most complete success crowned the efforts made by this country at the Universal Exhibition, and in one history of that wonderful pageant, Mr. Robin, the author, remarks : "the efforts made by Canada, that old French Colony, to make a suitable appearance at the great Exhibition of 1855, efforts which have resulted, moreover, in the most complete success, coupled with the undoubted importance of that fine country, whose future cannot be otherwise than brilliant, render it a duty on our part to devote to it a distinct chapter." Canada obtained one grand medal of honour (Sir W. Logan,) and is the only colony which secured that distinction-one medal of honour for the collection of woods and grains, thirteen silver medals, thirty bronze medals, and forty-eight 'honorable mentions,'-making altogether ninety-three prizes carried off at Paris, while at London the number of prizes awarded to this country amounted only to sixty-three. Mr. Romain's Steam Cultivator was not exhibited, it having been purchased and withdrawn from the exhibition by the celebrated

Agricultural Machine makers, Crosskill & Co., and is now designated as "Romain's Canadian Steam Cultivator."

Mr. Taché published in Paris his prize essay entitled "Esquisse sur la Canada consideré sous le point de vue économiste," - and in the report before us a translation of this little work is given. He also published a descriptive catalogue of the productions of Canada, exhibited in Paris in 1855, and at the end of each enumeration of articles embraced in the different classes, he gives their prices in this country, and appends remarks as to their distribution, commercial importance, &c. With reference to our progress in mining industry, we find that the exportations of metals from our mines was valued at £8,350 in 1852, and £74,000 in 1854. Attention is directed to the value of the 'Tamarack, as a serviceable wood, rapidly growing into favour in Europe. The oil of the black porpoise, Delphinus minor, is particularly noticed, on account of its remarkable property of retaining its fluidity at a very low temperature. Porpoise leather is altogether an article of Canadian manufacture, and possesses many valuable peculiarities. Birds'-eye maple was found to be excluded from general use in the Paris cabinet manufactories, on account of its price, and Mr. Taché very appropriately mentions the fact that it is used for fuel in Canada, and ought to be supplied at a price little above that of the commonest woods.

We are next furnished with "Observations on the Exhibition," which have already been published in the form of correspondence, addressed, during the exhibition, to a portion of the French Press of Lower Canada; these are republished in the Report, by order of the House of Assembly. Among many facts of interest to Canadians, contained in these instructive and attractive letters, we are told that the total area of the Crystal Palace at London, in 1851, was about 800,000 square feet—that of the Palace of Industry and its Annexe at Paris, exclusive of the Palace used for the exhibition of Fine Arts, 1,200,000 feet. The number of exhibitors at London was 14,840, at Paris 20,839.

Bearing in mind the depopulated condition of many of our Canadian rivers, which once swarmed with fish, Mr. Taché notices the illustrations of the new art of Pisciculture, and the specimens of young fry and spawn exhibited by Mr. Mallet, "who rears pike, carp, eels, &c., as other people do puppies." Various plans of fish-ways up mill dams are eminently suggestive, and ought to be introduced on every Canadian river where a dam is constructed, tending to oppose the upward progress of the fish in spawning time, and thus to depopulate our rivers. Mr. Letailleur's success in replacing rare furs by sheep skins prepared and dyed in various ways and colours, appears likely to commond itself to Canadian manufacturers.

Comparing the Canadian part of the Exhibition with its European rivals, Mr. Taché says :

"In the first class, embracing all that relates to the extraction of mineral substances, and to the minerals themselves, we were among the last, and far behind most countries, in regard to metallurgical operations, for the very simple reason that we are deficient in the population and capital which carry on, and still more deficient in the men of science, who in France, England, Austria, Prussia, Belgium, and other countries, direct and enlighten the labors of the mine. But if we proceed to an examination of the minerals in their natural state, our section at once assumed the first rank, and no country was in a condition to compete with us for a moment, either in the aggregate or the details of the department. The class of Canadian minerals was the most complete, and had the advantage of displaying at a glance to the learned observer the geological configuration of the country, with reference to the industrial results which it may yield. For this success, which is a mere repetition of that obtained at London in 1851, Canada is indebted entirely to the geological commissioners; and this shews to demonstration, the necessity of continuing the labors of that commission on a more liberal scale. We possess in the bosom of the earth the untouched riches, which in England have been the main element of industrial and commercial greatness; but the conditions of progress towards that greatness, are the light of science, and extensive enterprise. Mining operations cannot be profitably conducted on a small scale.

When we reflect that the iron which abounds in Canada is nearly of the same quality as that of Sweden, that it is found in places, surrounded by immense forests, and that, we have at hand the stone, sand, and other matters which are necessary for the smelting, moulding, and casting of the metal, we may well wonder that every year we import from England, Sweden, and the United States, manufactured iron to the amount of more than £1,000,000. But, we must again observe, success attends such enterprises, only when undertaken on a grand scale, whatever the abundance of the raw material. The working of an iron mine is not for limited means, nor to be carried on on a petty scale. A cheap market must be a full market. In Europe blast furnaces are now built, capable of smelting 80,000 lbs. per diem. The want of coke in Canada, be it observed, does not oppose an obstacle to the successful prosecution of iron-works. Ours is a country of rich forests 270,000 square miles in extent. Sweden smelts her iron with charcoal only, and sells it to England for a paying price; the English convert it into steel and send it to other countries. Other European countries use charcoal, notwithstanding the general scarcity and dearness of wood in Europe."

It appears also that "no country could compete with us in the show of woods, and particularly of the kinds used in ship-building, including in the estimate all the various species. In this class are embraced, moreover, all the products of the chase and the fisheries, in which departments the Gulf, and the vast territories of the Saguenay and the North-West, place us beyond competition, if not as producers, at least as proprietors of the finest field for production, in the whole world." The hints derived from an inspection of the raw material used by cabinet makers and carpenters among European nations, suggest very extensive alterations in the mode of getting out timber in our Canadian Forests, which deserve special notice.

"In lumbering, as the making of timber is termed in Canada, just that amount of intelligence is brought into action, which is required for the squaring of the logs, and the sawing of them into the planks of commerce. None of that skill of woodcraft is exercised which turns to the best and most profitable account the various species, by attending to their several degrees of adaptation to the mechanic arts, and to the preparation to be expended on them to make them fit for market. As before observed, two things only are known, square timber and the plank three inches thick. A more recondite study of the application of timber to the mechanic arts, would instruct us in the fact, that there are conditions of length, girth, and diameter required in those arts, by the influence of which the square log of 50 feet long by 20 inches square, and plank of 12 feet by 10 inches, lose their intrinsic value as compared with that higher value which is derivable from compliance with those conditions. How many are the trees left to rot in the forest because they are not reducible to a saw log of the standard measure, or a square stick of the required dimensions : which, trimmed to another form, would in other markets bear a greater value, though diminished in volume.

Of more than sixty principal species of timber which we possess, we make profitable use of scarcely ten, the rest are left to absolute decay. In Europe the birds'-eye maple is considered as equal to the most precious of the woods used in cabinet-work. It is indeed hardly attainable, and when found, it bears a higher price than mahogany. From this cause arises the dearness of all the articles made of maple in Parisian cabinet-work, the finest in the world."

Our agricultural productions when compared with those of other countries placed us on a level with the foremost : " our grain won the admiration of all who saw it." The absence of Hemp, Flax and Tobacco, however, was particularly noticed in the Canadian section, and our climate and soil were thought to furnish very favourable conditions for the cultivation of those valuable articles. It is not perhaps generally known by those who expressed surprise at the absence of Tobacco, that the late spring frosts to which our climate is subject, render the growth of Tobacco an expensive and very hazardous experiment. Where labour is very dear and sowing time very transient, it becomes a mere matter of calculation how far the growth of Tobacco may be made remunerative. It has often succeeded admirably in the western peninsula, but the occurrence of late frosts has not unfrequently destroyed the crops over wide areas and discouraged the cultivation of this important narcotic. Hemp and Flax give better promise of remunerative returns, and will no doubt soon form an important article of Canadian production.

37

Our castings did not meet with much favour, and the reasons may be drawn from the following observations by Mr. Taché :

"What lightness is found in the railings, the iron seats, &c., of the English manufacture of the Coalbrookdale Company in Shropshire, and how cheap also are the articles? The reason is plain, the purchaser has not to pay for a lot of useless iron."

"What elegance there is in the stoves and other articles of French manufacture, from the blast furnaces of the Marquis de Vogué of France? These designs of hunting and historical scenes are bas-reliefs of art, and the articles are not dearer on that account, because the material is not wasted; and as to the casting, the beautiful costs no more than the most deformed piece that ever was moulded. This is now generally understood; and in England where art is less perfect than in France and Belgium, the proprietors of foundries endeavour to procure artists from those two countries. A French sculptor, M. Geneste, is at this moment, in the receipt of a salary of £2000 per annum from an English manufacturer."

"The art of combining the useful with the agreeable is the climax of material progress. The study of the beautiful in art, is, to the intellectual man, what the study of truth is to his moral existence."

From many admirable inventions and applications which commend themselves to the attention of Canadians, and which are specially noticed with that object by Mr. Taché, we select some which appear likely to meet with adoption and favour. A smoke consuming coal grate, which is in the shape of an endless chain, and uncoils as the coal is consumed, thus combining advantages of health and economy. A machine by M. Chevalier, which by means of an endless steel wire adapted to pullies, saws with the greatest regularity the hardest stone, as quartz, granite, and even crystal. Two machines by M. Sautreuil. of Léchamp; one for preparing flooring boards by a single stroke. the other a planing machine, for smoothing timber for building purposes, on four sides at once. Messrs. Irey and Roly, of Paris, have introduced caoutchouc as a material for springs in all their machines. In the manufacture of chemical matches, for the production of an instantaneous light, Austria employs not less than 20,000 persons. and the highest price for round matches is only one penny per thousand. Mr. Quinti, of Vienna, showed how by interrupting the current by non-conductors, two communications may be transmitted simultaneously in opposite directions by the same wire. The preservation of food by the perfect exclusion of external air is easily accomplished by the immersion of game, or other meats, in a warm solution of gelatine. The celebrated Russia Leather is tanned with the decoction of willow bark, and impregnated with an oil extracted from the bark of the boulcau. A curious result of the artificial preparation of a valuable pigment is shown in the manufacture of Ultramarine. The nat-

# REVIEWS-REPORT OF THE SMITHSONIAN INSTITUTION. 39

tural mineral used to cost £75 per pound, and no more than four pounds were used in Europe in a year; now Europe manufactures and consumes 5,000,000 lbs. per annum, at a cost of one shilling per pound. One of the active principles in opium having been artificially produced there is no doubt but that quinine and other valuable medicinal agents will be prepared on a large and cheap scale in the laboratory. Vegetables may be prepared, for keeping by exposure to hot air and powerful compression, so that 1200 lbs. of dried vegetables may be packed into a space little exceeding a cube yard ; but 1200 lbs. of dried vegetables represent 8000 lbs. in their natural condition, which would require nearly forty cubic yards to contain them. The allied armies in the Crimea were provided with vegetables thus prepared to the extent of 42,000,000 rations. M. Coignet, of St Denis, exhibited a stone consisting of coal ashes and quick lime; or of sand, small shingle and lime : it is run like grouting. We may here observe that this method of building has long been practised in Amerca and even in the neighbourhood of Toronto.

It is unnecessary to advert to the "Sketch of the Geology of Canada," by Sir W. Logan and Mr. Hunt, or to the beautiful geological map accompanying the sketch, which are together appended to Mr. Taché's report, as these admirable and instructive illustrations of our mineral wealth have already been noticed in the Canadian Journal (new series, vol. i, p. 379.) We shall draw this brief summary of Mr. Taché's report to a close with a quotation from M. Fresca's work on the Exhibition; deeming it more satisfactory to receive and accept the testimony of a distinguished foreigner, than to express the favourable opinions of our great success at Paris which the perusal of Mr. Taché's report create.

"Canada," says M. Fresca, "is a land of hope not likely to be disapointed. Active, intelligent, and enterprising beyond all other nations, which equally abound in the elements of industral production, she claims and demands our attention."

H. Y. H.

The Tenth Annual Report of the Smithsonian Institution for the year 1855. Washington, 1856.

To such of our readers as are unacquainted with the origin and operation of this splendid establishment, the following brief notice may not be unacceptable:

# 40 REVIEWS-REPORT OF THE SMITHSONIAN INSTITUTION.

Hugh Smithson, from whom the institution derives its name, was a relative of the Duke of Northumberland. He was much devoted to physical science, and at Oxford, where he graduated, enjoyed the reputation of being the best chemist in the university. He was a cosmopolitan in his views, and used to express himself to the effect that the man of science belongs exclusively to no country; that the world is his country and all men are his countrymen. It was, it is believed, at one time his intention to leave his property to the Royal Society of London, for the promotion of science, but in consequence of a misunderstanding with the council of the society, he changed his mind and left it to his nephew, and, in case of the death of that relation without issue, to the United States of America, to found the institution which now bears his name.

In 1829 Smithson died, leaving his fortune, £120,000, in case of the death of his nephew, to whom it was first bequeathed, to found at Washington, under the name of the Smithsonian Institution, an establishment for the *increase* and *diffusion* of knowledge among men.

In 1838, the nephew having died, the money was paid over by the English Court of Chancery to the Agent appointed by the Government of the United States; and eight years afterwards, in 1846, an Act was passed through Congress for the establishment of the Smithsonian Institution.

By this Act the immediate government of the institution devolved upon the Board of Regents consisting of the following 15 members:

The Vice-President of the United States, the Chief Justice of the Supreme Court, the Mayor of the City of Washington, ex-officio; three members of the Senate, to be appointed by the President thereof; three members of the House of Representatives, appointed by the Speaker; six persons chosen from the citizens at large by joint resolution of the Senate and House, two of whom shall be members of the National Institute, and the other four inhabitants of states, and no two from the same state.

With a view of carrying the wishes of the testator into effect the Secretary, Professor Henry, was empowered to draw up a programme for the organization of the institution, which was presented in his first Annual Report to the Board of Regents and adopted by them in 1847.

As this programme is presented in the report before us we are enabled to give some extracts which serve to exhibit the principles that guide the governing body, as well as the mode of carrying the objects of the institution into effect.

"General considerations which should serve as a guide in adopting a plan of organization.

(1). Will of Smithson. The property is bequeathed to the United States of America to found at Washington, under the name of the SMITHSONIAN INSTITUTION, an establishment for the increase and diffusion of knowledge among men.

(2). The bequest is for the benefit of mankind. The Government of the United States is merely a trustee to carry out the design of the testator.

(3). The institution is not a national establishment, as is frequently supposed, but the establishment of an individual, and is to bear and perpetuate his name.

(4). The objects of this institution are, 1st., to increase, and 2nd, to diffuse, knowledge among men.

(5). These two objects should not be confounded with one another. The first is to enlarge the existing stock of knowledge by the addition of new truths; and the second, to disseminate knowledge, thus increased, among men.

(6). The will makes no restriction in favor of any particular kind of knowledge; hence all branches are entitled to a share of attention.

(13). It should be recollected that mankind in general are to be benefited by the bequest, and that, therefore, all unnecessary expenditure on local objects would be a perversion of the trust.

(14). Besides the forgoing considerations, deduced immediately from the will of Smithson, regard must be had to certain requirements of the Act of Congress establishing the institution. These are, a library, a museum, and a gallery of art, with a building on a liberal scale to contain them."

In order to carry out the two leading objects of the will of Mr. Smithson, the *increase*, namely, and the *diffusion* of knowledge, the same report recommends the following plans:

To *increase* knowledge one means proposed is to stimulate men of talent to make original researches by offering suitable rewards for memoirs containing new truths. The memoirs thus obtained are to be published in a series of volumes, and entitled Smithsonian Contributions to Knowledge.

Among the various objects of research named for which pecuniary appropriations may be made are included, a system of meteorological observations for solving the problem of American storms; Explorations in Natural History and Geology; Magnetic and Topographical Surveys; the solution of various experimental problems; and Statistical, Historical and Ethnological enquiries.

To promote the *diffusion* of knowledge the two leading means suggested are the publication of periodical reports on the progress of different branches of knowledge, and the publication occasionally of separate treatises.

For the preparation of these reports it is proposed that men

# 42 REVIEWS-BEPORT OF THE SMITHSONIAN INSTITUTION.

eminent in the respective branches be employed, that they be furnished with journals and other necessary publications, and that they be paid a certain sum for their labors.

In virtue of the Act of Congress, the Secretary and his assistants, during the session of Congress, will be required to illustrate new discoveries in science and to exhibit new objects of art; distinguished individuals will also be invited to give lectures on subjects of general interest.

On the occasion of the meeting of the Regents in 1847, it was resolved to divide the income into two equal parts; one to be appropriated to increase and diffuse knowledge agreeably to the scheme above given; and the other part to be appropriated to the formation of a library and a collection of objects of nature and of art.

This resolution was, however, rescinded at the meeting of January, 1855, when it was determined that

"The annual appropriations should be apportioned specially among the different objects and operations of the institution, in such manner as might, in the judgment of the Regents, be necessary and proper for each, according to its intrinsic importance, and a compliance in good faith with the law."

Admirably adapted as the foregoing scheme would seem to be for carrying out bona fide, the design of the founder, efforts have been made by some persons to divert from their legitimate channel the funds destined for cosmopolitan purposes, and to expend them on objects of a comparatively local character. The good sense and honorable feeling of the nation have, however, triumphed, and will, it is hoped, insure the permanence of the institution on its present footing. The mode of procedure adopted by the Regents in conducting the affairs of the institution having been brought under the notice of Congress in 1855, the matter was referred to a Special Committee of the House of Representatives and to the Judiciary Committee of the Senate. In reporting subsequently on the matter the Judiciary Committee unanimously approved of the acts of the Regents in construing the law of Congress, in interpreting the will of Smithson, and in what they had done in the way of increasing and diffusing knowledge among men.

In the verdict of the Judiciary Committee we find the following language:

(Referring to the legacy). "It is not bequeathed to the United States to be used for their own benefit and advantage only, but in trust to apply to the increase and diffusion of knowledge among mankind generally, so that other men and other nations might share in its advantages as well as ourselves." Again, in reference to the proposed application of the funds to the formation of a library, the Judiciary Committee go on to say:

"Such an application of the funds could hardly be regarded as a faithful execution of the trust; for the collection of an immense library at Washington would certainly not tend to increase or diffuse knowledge in any other country, not even among the countrymen of the testator; very few even of the citizens of the United States would receive any benefit from it.

" This is the construction which the Regents have given to the Acts of Congress, and in the opinion of the committee, it is the true one, and, acting under it, they have erected a commodious building, given their attention to all the branches of science mentioned in the law, to the full extent of the means afforded by the fund of the institution, and have been forming a library of choice and valuable books, amounting already to more than fiftcen thousand volumes. The books are, for the most part, precisely of the character calculated to carry out the intentions of the donor of the fund, and of the Act of Congress. They are chiefly composed of works published by or under the auspices of the numerous institutions of Europe which are engaged in scientific pursuits, giving an account of their respective researches and of new discoveries whenever they are made. These works are sent to the Smithsonian Institution in return for the publications of this institution which are transmitted to the learned societies and establishments abroad. The library thus formed, and the means by which it is accomplished, are peculiarly calculated to attain the objects for which the munificent legacy was given in trust to the United States. The publication of the results of scientific researches made by the institution is calculated to stimulate American genius, and at the same time enable it to bring before the public the fruits of its labors. And the transmission of these publications to the learned societies in Europe, and receiving in return the fruits of similar researches made by them, gives to each the benefit of the increase of knowledge which either may obtain, and at the same time diffuses it throughout the civilized world. The library thus formed will contain books suitable to the present state of scientific knowledge, and will keep pace with its advance; and it is certainly far superior to a wast collection of expensive works, most of which may be found in any public library, and many of which are mere objects of curiosity or amusement, and seldom, if ever, opened by any one engaged in the pursuit of science."

The Judiciary Committee conclude their report in the following terms :

"From the views entertained by the committee, after an impartial examination of the proceedings referred to, the committee have adopted the language of the resolution, 'that no action of the Senate is necessary and proper in regard to the Smithsonian Institution; and this is the unanimous opinion of the committee."

Having then briefly considered the origin, proposed objects and mode of action of this magnificent establishment, it remains for us to examine from the report for the year 1855 how far the proposed objects are in course of accomplishment.

The following are the principal contents of the report of the Regents for 1855;

# 44 REVIEWS-REPORT OF THE SMITHSONIAN INSTITUTION.

The Report of the Secretary to the Board of Regents; the Report of the Assistant Secretary and Curator; Reports of sub-committees relative to expenditure; Journals of meetings of the board; outlines of several lectures delivered in the rooms of the institution; directions to meteorological observers and various reports and suggestions relative to meteorological observations; correspondence relative to Ethnological and Topographical researches; and, finally, a long and able report on the present condition of the science of galvanism, by Professor Müller, of Freiburg, and translated from the German by Mr. Baker, of the Coast Survey.

# SECRETARY'S REPORT.

Among the memoirs which, in accordance with the announcement in the Secretary's Report, form the eighth volume of the Smithsonian Contributions are the following: along with others, by Major B. Alvord, and Dr. Joseph Jones; and a record of Auroral phenomena, by P. Force:

(1). On the progress of information and opinion respecting the archæology of the United States, by Samuel F. Haven, Librarian of the American Antiquarian Society.

(2). A paper on the recent secular period of the Aurora Borealis, by Professor Olmstead.

One useful function of the Smithsonian Institution is that of effecting literary and scientific exchanges between individuals and societies. The extent of their operations in this department may be judged of by the fact that in the year 1855, 8585 packages for distribution passed through the hands of the institution.

The Smithsonian agency is not confined to the transmission of works from the United States, but is extended to those of Canada and Central and South America, and its foreign relations embrace every part of the civilized world. It brings into friendly correspondence cultivators of original research the most widely separated, and emphatically realizes the idea of Smithson, that " the man of science is of no country;" that " the world is his country, and all mankind his countrymen."

The system of exchange has found favor with foreign governments, and the Smithsonian packages are now admitted into all parts to which they are sent, without detention and free of duty.

#### METEOROLOGY.

Since the publication of the former report an arrangement has been made with the Commissioner of Patents, by which the system of Meteorological observations established under the direction of the institution will be extended, and the results published more fully than the Smithsonian in some will allow.

With respect to the complaints that have been made that but few of the materials collected have been published, the report remarks, "It is more important that the information should be reliable than that it should be quickly published," and "what may be lost by delay is more than compensated by the precision and value of the results.

The reduction of the meteorological observations have been continued by Professor Coffin. He has completed the discussion of all the records for 1854, and those of 1855 as far as they have been sent in.

#### LIBRARY.

It is the present intention of the Regents to render the Smithsonian library the most extensive and perfect collection of Transactions and scientific works in this country, and this it will be enabled to accomplish by means of its exchanges, which will furnish it with all the current journals and publications of societies. The Institution has already more complete sets of transactions of learned societies than are to be found in the oldest libraries in the United States.

#### MUSEUM.

It is no part of the plan of the institution to form a Museum merely to gratify the curiosity of the casual visitor to the Smithsonian building, but it is the design to form complete collections in certain branches, which may serve to facilitate the study and increase the knowledge of natural history and geology.

With respect to the condition of the Museum, the report asserts that no collection of animals in the United States, nor indeed in the world, can even now pretend to rival the richness of this Museum in specimens which tend to illustrate the natural history of North America.

In the report of Professor Baird, the Assistant-Secretary, many details are given relative to the additions to the Museum. These additions have been made in great measure through the agency of the government exploring expeditions, and partly also through that of individuals under the orders of the institution.

### LECTURES.

The titles of the lectures, of which the substance is given in the volume before us, are as follows :

(2). A course of lectures on Marine Algæ, by W. H. Harvey, of the University of Dublin.

(2). Natural History as applied to farming and gardening, by Rev. J. G. Morris of Baltimore.

(3). Insect instincts and transformations, by the same.

(4). On oxygen and its combinations, by Professor Chase, of Brown University

(5). On meteoric stones, by Lawrence Smith, of the University of Louisville, Ky

(6). On planetary disturbances, by Professor Snell, of Amherst College.

The first lecture, by the Rev. Mr. Morris, on natural history as applied to farming and gardening, will be read with peculiar interest at the present time, when attention has been so much attracted to insect ravages on the corn crops. One practical evil, spoken of by the lecturer, arising from ignorance of the habits of insects, is that farmers and gardeners, by destroying one class of noxious animals,

### 46 REVIEWS-REPORT OF THE SMITHSONIAN INSTITUTION.

expose themselves to the ravages of more numerous and destructive creatures, whose numbers, the first, if suffered to live, would have kept within bounds. Speaking of one kind of moth, peculiarly hurtful to the vineyards in France, and of what may be done to check the evil if the habits of the creature be understood, he states that in twelve days from twenty to thirty women and children destroyed upwards of forty millions of eggs that would have been hatched in a few days. From the sketch of this lecture given, we are led greatly to regret that the abstract should not have had a greater space allotted to it than five pages.

LECTURE ON METEORIC STONES, BY DR. J. L. SMITH.

The lecturer distinctly maintains the lunar organ of meteoric stones. The discussion which, even in its abridged form, occupies twenty-four pages, is concluded in the following terms :

"To sum up the theory of the lunar origin of meteorites, it may be stated that "the moon is the only large body in space of which we have any knowledge, "possessing the requisite conditions demanded by the physical and chemical pro-"perties of meteorites; and that they have been thrown off by volcanic action, "(doubtless long since extinct) or some other disruptive force, and encountering "no gaseous medium of residence, reached such a distance as that the moon ex-"ercised no longer a preponderating attraction, the detached fragment possessing "an orbital motion and an orbital velocity, which it had in common with all parts of "the moon, but now more or less modified by the projectile force and new condi-"tion of attraction in which it was placed with reference to the earth, acquired "an independent orbit more or less elliptical. This orbit, necessarily subject to "great disturbing influences may sooner or later cross our atmosphere and be "intercepted by the body of the globe."

The lecture of Professor Snell is an able popular exposition of the subject of planetary disturbances.

### METEOROLOGY.

Of the matter contained in the present volume, that of the greatest importance on account of its immediate connection with a great scientific movement now in progress in Canada, is the body of directions for the meteorological observations adopted by the Smithsonian Institution. These instructions are well worthy of the study of all persons interested in this class of research.

Following the directions to observers is an account of a series of observations carried on, chiefly for the purpose of ascertaining the duration of thunder claps.

The Report of Professor Müller on galvanism, extending as it does through upwards of 100 closely printed pages, puts any attempt at analysis in our limited space utterly out of the question; we can only, therefore, refer our readers, for more ample details, to the pages of the work.

In laying down for the present the report of the Smithsonian Institution, (and it is with no little regret that we lay it down,) we derive our chief consolation from the recollection that it is not a solitary work, but one of a series, and that we may look forward to a renewal on each succeeding year of the enjoyment we have found in the perusal of the volume that we have just closed.

G. T. K.

# SCIENTIFIC AND LITERARY NOTES.

### GEOLOGY AND MINERALOGY.

### FOSSILS FROM ANTICOSTI.

During a recent visit to the Museum of the Geological Survey in Montreal, we were much gratified by the inspection of a fine collection of fossils, just received by Sir William Logan, from the Island of Anticosti. The greatest praise is due to Mr. Richardson, by whom, in the short space of a few months, this really magnificent collection was obtained. A preliminary examination by Professor Hall, of Albany, and Mr. Billings, the palæontologist attached to the Survey, has shewn the existence of a great number of new Brachiopods and other types—some, indeed, of a character at present altogether problematical. Amongst other facts of interest brought to light by the collection, we may mention the simultaneous occurrence in one of the Anticosti beds, of many well-marked forms belonging to both the Lower and Upper divisions of the Silurian series : a phenomenon not hitherto observed, or at least to a similar extent, in American rocks-the line of demarcation between the Upper and Lower Silurians of the Western World, being, as a general rule, very strongly pronounced. The lowest of the observed beds in Anticosti itself, belongs to the Hudson River Group; but the Sillery formation (the next in an ascending order) so largely developed along the Southern shores of the St. Lawrence, appears to be entirely wanting. Geologists may look forward with much interest, to the results of Professor Hall's detailed examination of this important addition to our knowledge of Palæozoic forms.

#### ASAPHUS LATIMARGINATUS.

#### [A. Canadensis-E. J. C.]

In the Canadian Journal for September of last year (vol. 1, p. 482), we called attention, under the name of Asaphus Canadensis, to a new form of Trilobite, from Whitby, in Canada West. Quite recently, we have received a letter from Professor Hall, in which that able paleeontologist suggests to us that the Trilobite in question is probably his Asaphus latimarginatus. Professor Hall states that the Museum of the Geological Survey of Canada has lately received some very perfect specimens of that species from the neighbourhood of Whitby; and he kindly promises us a drawing and revised description of his original species, for an ensuing number of the Journal. The only figures of Asaphus latimarginatus that we have had an opportunity of examining, consist merely of two more or less imperfect caudal shields given in the first volume of Hall's Palæontology of New York. Neither thorax nor buckler has, we believe, been hitherto figured or described at least beyond the brief description given in our note in the number of the Canadian Journal already alluded to. If the two forms prove to be identical, the original name of A. latimarginatus, as applied by Prof. Hall to the species founded on the two imperfect caudal shields figured by him in his Palæontology, must, of course, take the place of A. Canadensis, notwithstanding the appropriateness of the latter. Up to the present time, indeed, it is only in Canada that anything like complete specimens have been met with. The following is a description of the form to which our original remarks applied :

Cephalic shield pointed anteriorly, and in its general outline closely resembling that of  $Asaphus platycephalus^*$ , but with the posterior angles terminating in horns‡ which extend downwards to the bottom of the fourth thoracic segment. Facial sutures united in front at the extreme anterior margin of the buckler, and terminating as in A. platycephalus about midway between the glabella and the angles of the head-shield. Glabella very feebly raised; broad, and somewhat squared above; but without furrows of any kind. Eyes apparently as in A. platycephalus, but much destroyed in all the specimens examined. For dimensions, see below.

Thorax with eight segments. Pleuræ somewhat sabre-shaped (the curve upwards<sup>‡</sup>); grooved to about half their length from the axis outwards, and then crossed obliquely by a curvilinear ridge: the points of the pleuræ beyond the ridge, delicately striated.

Caudal shield with well developed axis: the axis tapering, and terminating rather abruptly before reaching the extremity of the pygidium; number of the rings not observable in the specimens examined.§ Pleuræ 14 in number, without grooves or ridges; bent downwards abruptly near the striated margin into which they merge. The lower ones, almost vertical.

Whole surface of the trilobite finely punctured, except at the striated limb. The punctures on the pleuræ, larger and farther apart than those on the axis. Also of a crescented or semi-circular form, with the convex and more deeply indented side turned inwards.

Relative (approximate) dimensions:—Assumed length of Buckler =1. Glabella, length =  $\cdot$  812. Thorax, length =  $\cdot$  875. Pygidium, length =  $1 \cdot 06$ . Middle lobe of Thorax, breadth =  $\cdot 50$  to  $\cdot 60$ . Outer lobes (each), breadth =  $\cdot 70$ . The small breadth of the middle lobe in relation to the side lobes, as compared with *Asa*phus platycephalus, appears to be of some importance, unless it be a mere sexual

<sup>\*</sup> Isotelus gigas, Auct.

<sup>+</sup> This part of the head-shield is very obscure in the specimens hitherto examined. We were led at first to believe that the angles were rounded.

<sup>&</sup>lt;sup>‡</sup> This, however, is only to be seen when the pleuræ have become accidentally separated to a certain extent from one another.

<sup>§</sup> Since the above description was written, the son of His Excellency the Governor General, has kindly submitted to us some specimens obtained by him personally from the Whitby quarries. In one of these, the pygidium of a young individual, fourteen rings may be counted in the axis.

difference. Where, however, the pleuræ are bent, the length of the side lobes can rarely be estimated with any great exactness.

The average adult size of these trilobites appears to be about  $4\frac{1}{2}$  inches in length, by about 3 inches in breadth; but, judging from isolated fragments, larger individuals no doubt occur. Many of the Whitby specimens, at the same time, are much below the above dimensions. Most of them are converted into iron pyrites. The *Asaphus Barrandi* of Hall appears to be a closely related species.

#### FOSSILS FROM ALTERED ROCKS IN EASTERN MASSACHUSETTS.

A very interesting discovery of a trilobite—a species of Paradoxides—in the metamorphic rocks of Quincy and Baintree, about ten miles South of Boston, has just been announced to the scientific world, by Professor W. B. Rogers. The true place of these rocks, hitherto of uncertain paleozoic range, would thus appear to belong to quite the base of the Silurian series: at least if the trilobite in question be really a paradoxides—in which case, it will also be of interest, as constituting the first true species of that genus met with in American rocks since the announcement of Green's debatable *Paradoxides Harlani* in 1832. Full particulars of this discovery will be found in the last October number of the Edinburgh New Philosophical Journal; and in the Proceedings of the Natural History Society of Boston, for the same month.

#### BURR-STONE.

A curious deposit of Burr-stone, constituting a vein of considerable thickness, has lately been discovered by Sir William Logan, in the gneiss of Chatham, in Canada East. The stone, probably a siliceous deposit from heated waters, occurs, according to Sir William, in close association with several complicated veins of igneous rock of at least three different periods of formation. As the stone is of excellent quality, and readily obtainable, the discovery—apart from the scientific interest belonging to the mode of occurrence of the deposit—is one of no little importance. Specimens may be seen in the Museum of the Geological Survey at Montreal.

#### RED OXIDE OF COPPER.

Mr. James Gilbert, lately returned from California, has presented to the Institute, some specimeus of red copper ore from the Arizona mines, 110 miles S. E. of Fort Yunia, and about 35 miles from the River Gila. As samples, the specimens are extremely rich, being almost free from rock matter. They contain small strings of native copper, from which the Cu<sup>2</sup>O has evidently been derived; and by a further process of alteration, the ore is converted externally, into malachite. The occurrence of red copper in California has not hitherto been announced in any of our treatises on Mineralogy. We are ignorant of its geological associations.

#### VANADINITE.

In the last number of the *Journal*, (vol. 1, page 553), an analysis, by Rammelsberg, of Vanadinite from Windisch-Kappel, was given; the results of which lead to the inference that  $VO^3$  and  $PO^5$  are isomorphous. Adolf Kengott, (in Poggendorff's Annalen, 1856, No. 9), has subjected this analysis to a very elaborate discussion, in which he seeks to maintain that the loss of 3.21 per cent. therein exhibited, must be due to some cause other than accidental. To account for this loss, he assumes the original existence in the mineral of the hypothetical com-VOL. II.---D

pound  $\nabla O^{5}$ . Rammelsberg's analysis gave 17.41 per cent. of  $\nabla O^{3}$ : a value corresponding to 20.31 per cent. of  $\nabla O^{5}$ . In this manner the total results of the analysis are brought up to 99.69; and the isomorphism of Vanadinite with Pyromorphite satisfactorily explained. Before this view can be received, however, it will be for the chemist to determine if there be any real grounds for the assumption of the existence of this higher oxygen compound. So far as present researches go, the tendency of vanadic acid,  $\nabla O^{3}$ , would appear to be altogether towards reduction. The question, however, here, is not the conversion of  $\nabla O^{3}$  into  $\nabla O^{5}$ , but the reverse: a process which we might readily conceive to take place, were the existence of the latter compound allowed to be probable.

E. J. C.

### THE BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

#### CHELTENHAM, 6th August, 1856.

After the requisite preliminary business, conducted by the General Committee of the Association, and including the reading of the Report of the Council, and of that of the Kew Committee, the body of members assembled to witness the resignation of the Chair by the Duke of Argyle, to his successor, Professor Daubeny, and to hear the President's Address. On this occasion the occupation of the Chair of the British Association by one not only distinguished as a Chemist, but by one who is no less eminent as a Botanist, gave a new character to the Presidential Address. After some preliminary remarks of a personal nature, Dr. Daubeny proceeded with his address, from which we have only room for a brief selection of passages of special interest. Referring to the British Association as alike valuable as an efficient instrument for the furtherance of scientific objects, and as a model after which other associated scientific bodies have been organized, the President thus proceeded:

It is rather remarkable that the first idea of an Association of such a kind should have suggested itself only a year after death had deprived us of our three most distinguished philosophers :- for who had we then left to compare with Davy for the brilliancy and importance of his discoveries ; with Young for the singular union of almost universal acquirements with admirable powers of invention; and with Wollaston for an acuteness of mental vision, which gave him the same advantage in the pursuits of science which the naturalist, armed with a microscope has over the unassisted observer ? Just as in the animal economy the vis medicatrix nature sometimes makes an extraordinary effort to repair the damage inflicted by injury or disease, so it would seem as if Science, conscious of the loss she had sustained in the almost simultaneous extinction of her three brightest luminaries. endeavoured to make good the deficiency by concentrating into one focus those that yet remained, to light her onwards on her path. At any rate, the progress which the Natural Sciences have made since that period, although doubtless attributable to several concurrent causes, is a fact which must not be overlooked in estimating the services rendered by this Association to the cause of human advancement; nor can I in any better manner point out its value than by bringing before your notice a few of the additions to our knowledge which have been made since I last addressed you.

Beginning then with Chemistry, as the subject with which I am most familiar, let me remind you, that at a period not much more remote than the one alluded to, all of it that could be quoted as really worthy the name of a science was comprehended within the limits of the mineral kingdom. Here at least the outline had been traced out with sufficient precision-the general laws established on a firm basis-the nomenclature framed with logical exactness-the facts consistent with each other, and presented in a scientific and luminous form. Thus a philosopher, like Sir Humphrey Davy, who had contributed in so eminent a degree to bring the science into this satisfactory condition, might, at the close of his career, have despaired of adding anything worthy of his name to the domain of chemistry, and have sighed for other worlds to subdue. But there was a world almost as little known to the chemists of that period as was the Western Hemisphere to the Mace. donian Conqueror, --- a World comprising an infinite variety of important products, called into existence by the mysterious operation of the vital principle, and therefore placed, as was imagined, almost beyond the reach of experimental research. This is the new World of Chemistry, which the Continental philosophers in the first instance, and subsequently those of our own country, have during the last twenty years been busy in exploring, and by so doing have not only bridged over the Gulf which had before separated by an impassable barrier the kingdoms of inorganic and of organic nature, but also have added provinces as extensive and as fertile as those we were in possession of before, to the partrimony of Science.

It is indeed singular, that whilst the supposed elements of mineral bodies are very numerous, the combinations between them should be comparatively few; whereas amongst those of vegetable and animal origin, where the ultimate elements are so limited in point of number, the combinations which they form appear almost infinite. Carbon and hydrogen, for instance, constitute, as it were, the keystone of every organic fabric; whilst oxygen, nitrogen, and less frequently sulphur and phosphorus, serve almost alone to build up their superstructure. And yet what an infinity of products is brought about by ringing the changes upon this scanty alphabet! Even one series of bodies alone, that known by the name of the Fatty Acids, comprises several hundred well-ascertained combinations, founded however upon a single class of hydro-carbons or compound radicals, in which the carbon and hydrogen stand to each other in equal atomic proportions, and are in each case acidified by the same number of equivalents of oxygen. These acids are all monobasic, or combine with only one proportion of base; but add to any one of them two equivalents of carbonic acid, and you obtain a member of a second series, which is bibasic, or is capable of forming two classes of salts. The above therefore constitute a double series, as it were, of organic acids, the members of which are mutually related in the manner pointed out, and differ from each other in their mode of combining according to the relation between their respective elements. But already, by the labours of Hofmann and of other chemists, two other double series of acids, the one monobasic, the other bibasic, mutually related exactly in the same manner as those above, have been brought to light; each series no doubt characterized by an equally numerous appendage of alcohols, of æthers, and of aldehydes, to say nothing of the secondary compounds resulting from the union of each of these bodies with others.

Hence the more insight we obtain into the chemistry of organic substances the more we become bewildered with their complexity, and in investigating these phe-

nomena, find ourselves in the condition of the explorer of a new continent, who, although he might see the same sun over his head, the same ocean rolling at his feet, the same geological structure in the rocks that were piled around him, and was thus assured that he still continued a denizen of his own planet, and subject to those physical laws to which he had been before amenable, yet at every step he took was met by some novel object, and startled with some strange and portentous production of Nature's fecundity. Even so the chemist of the present day, whilst he recognizes in the world of organic life the same general laws which prevail throughout the mineral kingdom, is nevertheless astonished and perplexed by the multiplicity of new bodies that present themselves, the wondrous changes in them resulting from slight differences in molecular arrangement, and the simple nature of the machinery by which such complicated effects are brought about. And as the New World might never have been discovered, or, at all events, would not have been brought under our subjection, without those improvements in naval architecture which had taken place prior to the age of Columbus, so the secrets of organic chemistry would have long remained unelicited, but for the facilities in the methods of analysis which were introduced by Liebig. Before his time the determination of the component elements of an organic substance was a task of so much skill as well as labour, that only the most accomplished analysts-such men, for instance, as my lamented friend Dr. Prout in this country, or as the great Berzelius in Sweden-could be depended upon for such a work; and hence the data upon which we could rely for deducing any general conclusions went on accumulating with extreme slowness. But the new methods of analysis invented by Liebig have so simplified and so faciliated the processes, that a student, after a few months' practical instruction in a laboratory, can, in many instances, arrive at results sufficiently precise to be made the basis of calculation, and thus to enable the master mind, which is capable of availing itself of the facts before it, to breathe life into these dry numerical details,-just as the sculptor, by a few finishing stokes, brings out the expression of the statue, which has been prepared for him by the laborious chiselling of a number of subordinate workmen. And as the established laws and institutions of the Old World have been modified-may I not say in some instances rectified ?---by the insensible influence of those of the New, so have the principles that had been deduced from the phenomena of the mineral kingdom undergone in many instances a correction from the new discoveries made in the chemistry of the animal and vegetable creation. It was a great step indeed in the progress of the science, when Lavoisier set the example of an appeal to the balance in all our experimental researches, and the Atomic Theory of Dalton may be regarded as the necessary, although somewhat tardy, result of the greater numerical precision thus introduced. But no less important was the advance achieved, when structure and polarity were recognized as influencing the condition of matter; and when the nature of a body was felt to be determined, not only by the condition of its component elements, but also by their mutual arrangement and collocation-a principle which, first illustrated amongst the products of organic life, has since been found to extend alike to all chemical substances whatever.

Formerly it had been the rule to set down the bodies which form the constituents of the substances we analyzed, and which had never yet under our hands undergone decomposition, as elementary; but the discovery of cyanogen in the first instance, and the recognition of several other compound radicals in organic chemistry more lately, naturally suggest the idea that many of the so-called elements of inorganic matter may likewise be compounds, differing from the organic radicals above mentioned merely in their constituents being bound together by a closer affinity. And this conjecture is confirmed by the curious numerical relations subsisting between the atomic weights of several of these supposed elements; as, for example, between chlorine, bromine and iodine : an extension of the grand generalization of Dalton, which, although it was unforeseen by the Founder of the system, and therefore, like Gay-Lussac's Theory of Volume, might very possibly have been repudiated by him, had it been proposed for his acceptance, will be regarded by others as establishing, in a manner more conclusive than before, the soundness of his antecedent deductions. What, indeed, can be a greater triumph for the theorist, than to find that a law of nature which he has had the glory of establishing by a long and painful process of induction, not only accommodates itself to all the new facts which the progress of discovery has since brought to light, but is itself the consequence of a still more general and comprehensive principle, which philosophers, even at this distance of time, are still engaged in unfolding ?

\* \* \* \* \* \* \* \* \* \* \* \* \*

But passing over speculations which have not as yet received the general assent of chemists, let me advert to others of an older date, possessing as I conceive, the strongest internal evidence in their favour, which the case admits, from the harmony they tend to introduce into the chaos of facts which the late discoveries in organic chemistry have brought to light. Amongst these, one of the most generally received, and at the same time one of the most universal application, is that which represents the several combinations resulting from organic forces, as being put together according to a particular model or type, which impresses upon the aggregate formed certain common properties, and also causes it to undergo change most readily, through the substitution of some other element in the place of one of those which already enters into its constitution. And this principle, having been established with regard to one class of bodies, has since been extended to the rest; for it now begins to be maintained, that in every case of chemical decomposition a new element is introduced in the place of one of those which constituted a part of the original compound, so that the addition of a fresh ingredient is necessarily accompanied by the elimination of an old one. The same doctrine, too, has even been extended to the case of combination with a body regarded as elementary, for here also the particles are considered as being in a state of binary combination one with the other, owing perhaps to their existing in opposite electrical conditions, and therefore possessing for each other a certain degree of chemical affinity. Thus, when we unite hydrogen with oxygen, we substitute an atom of the latter for one of the former, previously combined with the same element.

To the microscope we owe all that is as yet known with respect to the reproductive process in cryptogamous plants, which are now shown to possess a structure analogous to that of flowering ones in respect to their organs of reproduction; not, indeed, as Hedwig supposed, that parts corresponding to stamens and pistils in appearance and structure can be discovered in them, but that as the primary distinction of sexes seems to run throughout the Vegetable Kingdom, new parts are superadded to a structure common to all as we ascend in the scale of creation, until from the simple cell, which, in consequence of some differences of structure, to our eyes inappreciable, appears to exercise in one case the function of the male, in another of the female, as is found the case in certain of the Confervæ, we arrive

米

\*

\* \* \*

at length at the complicated machinery exhibited in flowering plants, in which the cell containing the fecundating principle is first matured in the stamen, and afterwards transmitted, through an elaborate apparatus, to the cells of the ovule, which is in like manner enveloped in its matrix, and protected by the series of investing membranes which constitutes the seed-vessel. Thus, as Goethe long ago observed. and as modern physiologists have since shown to be the case, the more imperfect a being is, the more its individual parts resemble each other-the progress of development, both in the Animal and Vegetable Kingdoms, always proceeding from the like to the unlike, from the general to the particular. But whilst the researches of Brown and others have shown that there is no abrupt line of division in the Vegetable Kingdom, and that one common structure pervades the whole, the later inquiries of Suminski, Hofmeister, Unger, Griffith, and Henfrey, have pointed out several curious and unlooked-for analogies between plants and animals. I may mention, in the first place, as an instance of this analogy between plants and animals, the existence of moving molecules, or phytosperms, in the antheridia of ferns and other Cryptogams, borne out, as it has been in so remarkable a manner, by the almost simultaneous observations of Bischoff and Meissner on the egg, confirmatory of those formerly announced by Barry and Newport, and by the researches of Suminski, Thurst, and Pringsheim, with respect to the ovule of plants. I may refer you also to a paper read at the last Meeting of the Association, by Dr. Cohn, of Breslau, who, in bringing this subject before the Natural History Section, adduced instances of a distinction of sexes which had come under his observation in the lower Algæ. In like manner a curious correspondence has been traced between the lower tribes of animals and plants, in the circumstance of both being subject to the law of what is called alternate generation. This consists in a sort of cycle of changes from one kind of being to another, which was first detected in some of the lower tribes of animals; a pair of insects, for example, producing a progeny differing from themselves in outward appearance and internal structure, and these reproducing their kind without any renewed sexual union,-the progeny in these cases consisting of females only. At length, after a succession of such generations, the offspring reverts to its primæval type, and pairs of male and female insects, of the original form, are reproduced, which complete the cycle, by giving rise in their turn to a breed presenting the same characters as those which belong to their own progenitors. An ingenious comparison had been instituted by Owen and others between this alternation of generations in the animal, and the alternate production of leaves and blossoms in the plant; but the researches to which I especially allude have rendered this no longer a matter of mere speculation or inference, inasmuch as they have shown the same thing to occur in ferns, in lycopodia, in mosses, nay, even in the confervæ. We are indebted to Prof. Henfrey for a valuable contribution to our Transactions in 1851 on these subjects, given in the form of a Report on the Higher Cryptogamous Plants; from which it at least appears that the proofs of sexuality in the Cryptogamia rank in the same scale, as to completeness, as those regarding flowering plants did before the access of the pollen tubes to the ovule had been demonstrated. Indeed, if the observations of Pringsheim with respect to certain of the Algæ are to be relied upon, the analogy between the productive process in plants and animals is even more clearly made out in these lower tribes than it is in those of higher organization. It also appears that the production in ferns and other Acrogens of what has been callled a pro-embryo; the evolution of antheridia and archegonia, or of male and female organs, from the former; and the generation from the archegonia

of a frond bearing spores upon its under surface, is analogous to what takes place in flowering plants in general; where the seed, when it germinates, produces stem, roots, and leaves; the stem for many generations gives rise to nothing but shoots like itself; until at length a flower springs from it, which contains within itself for the most part the organs of both sexes united, and, therefore, occasions the reproduction of the same seed with which the chain of phenomena commenced. This is the principle which a learned Professor at Berlin has rather obscurely shadowed out in his treatise on the Rejuvenescence of Plants, and which may perhaps be regarded as one, at least, of the means by which Nature provides for the stability of the forms of organic life she has created, by imparting to each plant a tendency to revert to the primeval type.

To the elder De Candolle we are also indebted for some of our most philosophical views with respect to the laws which regulate the distribution of plants over the globe,--views which have been developed and extended, but by no means subverted, by the investigations of subsequent writers; amongst whom Sir Charles Lyell, in his 'Principles of Geology,' and the younger De Candolle, a worthy inheritor of his father's reputation, in his recently published work on Botanical Geography, have espescially signalized themselves. But it is to the late Prof. Edward Forbes, and to Dr. Joseph Hooker, that we have principally to attribute the removal of those anomalies, which threw a certain degree of doubt upon the principles laid down by De Candolle in 1820, in his celebrated article on the Geography of Plants, contained in the 'Dictionnaire des Sciences Naturelles,' where the derivaion of each species from an individual, or a pair of individuals, created in one particular locality, was made the starting point of all our inquiries. These anomalies were of two different kinds, and pointed in two opposite directions: for we had in some cases to explain the occurrence of a peculiar Flora in islands cut off from the rest of the world, except through the medium of a wide intervening ocean; and in other cases to reconcile the fact of the same or of allied species being diffused over vast areas, the several portions of which are at the present time separated from each other in such a manner, as to prevent the possibility of the migration of plants from one to the other. Indeed, after making due allowances for those curious contrivances by which Nature has in many instances provided for the transmission of species over different parts of the same continent, and even across the ocean, and which are so well pointed out in De Candolle's original essay, we are compelled to admit the apparent inefficiency of existing causes to account for the distribution of the larger number of species; and must confess that the explanation fails us often where it is most needed, for the Compositæ in spite of those feathery appendages they possess, which are so favorable to the wide dissemination of their seeds, might be inferred, by their general absence from the fossil Flora, to have diffused themselves in a less degree than many other families have done. And on the other hand, it is found, that under existing circumstances, those Compositæ, which are disseminated throughout the area of the Great Pacific, belong in many cases to species destitute of these auxiliaries to transmission. But here Geology comes to our aid; for by pointing out the probability of the submergence of continents on the one hand, and the elevation of tracts of land on the other, it enables us to explain the occurrence of the same plants in some islands or continents now wholly unconnected, and the existence of a distinct Flora in others too isolated to obtain it under present circumstances from without. In the one case we may suppose the plants to have been distributed over the whole area before its several parts became

disunited by the catastrophes which supervened; in the other, we may regard the peculiar Flora now existing as merely the wreck, as it were, of one which once overspread a large tract of land, of which all but the little patch on which it is now found had been since submerged. Upon this subject our opinions may in some measure be swayed by the nature of the conclusion we arrive at with respect to the length of time during which seeds are capable of mantaining their vitality; for if after remaining for an indefinite period in the earth they were capable of germinating, it would doubtless be easier to understand the revival, under favorable circumstances, of plants which had existed before the severance of a tract of land from the continent in which they are indigenous. An inquiry has accordingly been carried on for the last fifteen years under the auspices of, and with the aid of funds supplied by, this Association, the results of which, it is but fair to say, by no means corroborate the reports that had been from time to time given us with respect to the extreme longevity of certain plants, exemplified, as it was said, in the case of the mummy-wheat and other somewhat dubious instances; inasmuch as they tend to show, that none of the seeds which were tested, although they were placed under the most favorable artificial conditions that could be devised, vegetated after a period of forty-nine years; that only twenty out of 288 species did so after twenty years; whilst by far the larger number had lost their germinating power in the course of ten. These results, indeed, being merely negative, ought not to outweigh such positive statements on the contrary side as come before us recommended by respectable authority, such, for instance, as that respecting a Nelumbium seed, which germinated after having been preserved in Sir Hans Sloane's Herbarium for 150 years ; still, however, they throw suspicion as to the existence in seeds of that capacity of preserving their vitality almost indefinitely, which alone would warrant us in calling to our aid this principle in explaining the wide geographical range which certain species of plants affect.

or plants a

\* \*

Amongst the many services rendered to the Natural Sciences by Dr. Hooker, in conjunction with his fellow traveller, Dr. Thomson, one of the greatest I conceive to be, that they have not only protested against that undue multiplication of species, which had taken place by exalting minute points of difference into grounds of radical and primary distinction, but that they have also practically illustrated their views with respect to the natural families which have been described by them in the volume alluded to. They have thus contributed materially to remove another difficulty which stood in the way of the adoption of the theory of specific centres, —I mean the replacement of forms of vegetation in adjoining countries by others, not identical, but only as it should seem allied; for it follows from the principles laid down by these authors, that such apparently distinct species may after all have been only varieties, produced by the operation of external causes acting upon the same species during long periods of time.

34

But if this be allowed, what limits, it may be asked, are we to assign to the changes which a plant is capable of undergoing,—and in what way can we oppose the principle of the transmutation of species, which has of late excited so much attention, and the admission of which is considered to involve such startling consequences? I must refer you to the writings of modern physiologists for a full discussion of this question. All that I shall venture to remark is, that had not Nature herself assigned certain boundaries to the changes which plants are capable of undergoing, there would seem no reason why any species at all should be restricted

within a definite area, since the unlimited adaptation to external conditions which it would then possess might enable it to diffuse itself throughout the world, as easily as it has done over that portion of space within which it is actually circumscribed. Dr. Hooker instances certain species of Coprosma, of Celmisia, and a kind of Australian Fern, the Lomaria procera, which have undergone such striking changes in their passage from one portion of the Great Pacific to another, that they are scarcely recognizable as the same, and have actually been regarded by preceding botanists as distinct species. But he does not state that any of these plants have ever been seen beyond the above-mentioned precincts; and yet if Nature had not imposed some limits to the suscptibility of change, one does not see why they might not have spread over a much larger portion of the earth, in a form more or less modified by external circumstances. The younger De Candolle, in his late admirable treatise already referred to, has enumerated about 117 species of plants which have been thus diffused over at least a third of the surface of the globe, but these apparently owed their power of transmigration to their insusceptibility of change, for it does not appear that they have been much modified by the effect of climate or locality, notwithstanding the extreme difference in the external conditions to which they were subjected. On the other hand, it seems to be a general law, that plants whose organization is more easily affected by external agencies become from that very cause, more circumscribed in their range of distribution; simply because a greater difference in the circumstances under which they would be placed brought with it an amount of change in their structure which exceded the limits prescribed to it by Nature. In short, without pretending to do more thanto divine the character of those impediments, which appear ever to prevent the changes of which a plant is suceptible from proceeding beyond a certain limit, we seem to catch a glimpse of a general law of Nature, not limited to one of her kingdoms, but extending everywhere throughout her jurisdiction, -a law, the aim of which may be inferred to be that of maintaining the existing order of the universe, without any material or permanent alteration, throughout all time, until the fiat of Omnipotence has gone forth for its destruction. The will which confines the variations in the vegtable structure within a certain range, lest the order of creation should be disturbed by the introduction of an indefinite number of intermediate forms is apparently the same in its motive as that which brings back the celestial luminaries to their original orbits, after the completion of a cycle of changes induced by their mutual perturbations; it is the same which says to the ocean, Thus far shalt thou go, and no further; and to the winds, Your violence, however apparently capricious and abnormal, shall nevertheless be constrained within certain prescribed limits-

> Ni faciat, maria et terras cœlumque profundum, Quippe ferant rapidi secum, verrantque per auras.

The whole, indeed, resolves itself into, or at least is intimately connected with, that law of symmetry to which Nature seems ever striving to conform, and which possesses the same significance in the organic world, which the law of definite proportions does in the inorganic. It is the principle which the prophetic genius of Goethe had divined, long before it had been proved by the labours of physiologists to be a reality, and to which the poet attached such importance, that the celebrated discussion as to its merits which took place in 1830 between Cuvier and Geoffry St. Hilaire so engrossed his mind, as to deprive him, as his biographer informs us, of all interest in one of the most portentous political events of modern days which was enacting at the very same epoch,—I mean the subversion of the Bourbon dynasty.

It is, indeed, not less calculated to subserve to the gratification of our sense of the Beautiful than to provide against too wide a departure from that order of creation which its great Author has from the beginning instituted; and, as two learned Professors of a sister kingdom have pointed out in Memoirs laid before this Association, and have since embodied in a distinct treatise, manifests itself not less in the geometrical adjustment of the branches of a plant, and of the scales of a fir-apple -nay even, as they have wished to prove, in the correspondence between the form of the fruit and that of the tree on which it grows-than in the frequent juxtaposition of the complimentary rays of the spectrum, by which that harmony of colour is produced in Nature which we are always striving, however unsuccessfully, to imitate in Art. The law, indeed, seems to be nothing else than a direct consequence of that unity of design pervading the universe, which so bespeaks a common Creator-of the existence in the mind of the Deity of a sort of archetype, to which His various works have all, to a certain extent, been accommodated ; so that the earlier forms of life may be regarded as types of those of latter creation, and the more complex ones but as developments of rudimentary parts existing in the more simple.

I might be disposed to claim for the recent investigations of botanists some share in fixing the relative antiquity of particular portions of the globe, for from the Floras they have given us of different islands in the Great Pacific, it would appear that the families of plants which characterize some groups are of a more complicated organization than those of another. Thus, whilst Otaheite chiefly contains Orchids, Apocyneæ, Asclepiadeæ, and Urticeæ; the Sandwich Islands possess Lobeliaceæ and Goodenoviæ; and the Galapagos Islands, New Zealand and Juan Fernandez, Compositæ, the highest form, perhaps, of dicotyledonous plants. In deducing this consequence, however, I am proceeding upon a principle which has lately met with opposition, although it was formerly regarded as one of the axioms in Geology. Amongst these, indeed, there was none which a few years ago seemed so little likely to be disputed as that the classes of animals and vegetables which possessed the most complicated structure were preceded by others of a more simple one; and that when we traced back the succession of beings to the lowest and the earliest of the sedimentary formations, we arrived at length at a class of rocks, the deposition of which must be inferred, from the almost entire absence of organic remains, to have followed very soon after the first dawn of creation. But the recognition of the footsteps and remains of reptiles in beds of an earlier date than was before assigned to them, tended to corroborate the inferences which had been previously deduced from the discovery, in a few rare instances, in rocks of the secondary age, of mammalian remains; and thus has induced certain eminent geologists boldly to dispute, whether from the earliest to the latest period of the earth's history any gradation of beings can in reality be detected. Into this controversy I shall only enter at present, so far as to point out an easy method of determining the fact, that organic remains never can have existed in a particular rock, even although it may have been subjected to such metamorphic action as would have obliterated all traces of their presence. This is simply to ascertain that the material in question is utterly destitute of phosphoric acid; for inasmuch as every form of life appears to be essentially associated with this principle, and as no amount of heat would be sufficient to dissipate it when in a state of combination, whatever quantity of phosphoric acid had in this manner been introduced into the rock, must

have continued there till the end of time, notwithstanding any igneous operations which the materials might have afterwards undergone. But as the discovery of very minute traces of phosphoric acid, when mixed with the other ingredients of a rock, is a problem of no small difficulty, an indirect method of ascertaining its presence suggested itself to me in some experiments of the kind which I have instituted, namely, that of sowing some kind of seed, such for instance as barley, in a sample of the pulverized rock, and determining whether the crop obtained yielded more phosphoric acid than was present in the grain, it being evident that any excess must have been derived from the rock from which it drew its nourishment. Should it appear by an extensive induction of particulars, that none of the rocks lying at the base of the Silurian formation, which have come before us, contain more phosphoric acid than the minute quantity I detected in the slates of Bangor and Llanberris, which were tested in the above manner, it might perhaps be warrantable hereafter to infer that we had really touched upon those formations, that had been deposited at a time when organic beings were only just beginning to start into existence, and to which therefore, the term Azoic, assigned to these rocks by some of the most eminent of our geologists, might not be inappropriate. The proofs of the former extension of glaciers in the Northern hemisphere, far beyond their actual limits, tend also to complicate the question which has at all times so much engaged the attention of cosmogonists with respect to the ancient temperature of the earth's surface, compelling us to admit that, at least during the latter of its epochs, oscillations of heat and cold must have occurred, to interfere with the progress of refrigeration which was taking place in the crust. On the other hand, facts of an opposite tendency, such as the discovery announced at our last meeting by Capt. Belcher, of the skeleton of an Ichthyosaurus in lat. 77°, and of the trunk of a tree standing in an erect position in lat. 75°, have been multiplying upon us within the same period; inasmuch as they appear to imply, that a much higher temperature in former times pervaded the Arctic regions that can be referred to local causes, and therefore force upon us the admission, that the internal heat of the nucleus of our globe must at one time have influenced in a more marked manner than at present the temperature of its crust.

\* \* \* \* \* \* \*

Twenty years ago it was thought necessary to explain at our meetings the character and objects of this Association, and to vindicate it from the denunciations fulminated against it by individuals, and even by parties of men, who held it up as dangerous to religion, and subversive of sound principles in theology. Now so marked is the change in public feeling, that we are solicited by the clergy, no less than by the laity, to hold our meetings within their precincts; and we have never received a heartier welcome than in the city in which we are now assembled, which values itself so especially, and with such good reason, on the extent and excellence of its educational establishments. It begins, indeed, to be generally felt, that amongst the faculties of the mind, upon the development of which in youth success in after life mainly depends, there are some which are best improved through the cultivation of the Physical Sciences, and that the rudiments of those sciences are most easily acquired at an early period of life. That power of minute observation -those habits of method and arrangement-that aptitude for patient and laborious inquiry-that tact and sagacity in deducing inferences from evidence short of demonstration, which the Natural Sciences more particularly promote, are the fruits of early education, and acquired with difficulty at a later period. It is during child-

hood, also, that the memory is most fresh and retentive and that the nomenclature of the sciences, which, from its crabbedness and technicality, often repels us at a more advanced age, is acquired almost without an effort. Although, therefore it can hardly be expected that the great schools in the country will assign to the Natural Sciences any important place in their systems of instruction until the Universities for which they are the seminaries set them the example, yet I cannot doubt but that, the signal once given, both masters and scholars will eagerly embrace a change so congenial to the tastes of youth, and so favorable to the development of their intellectual faculties. And has not, it may be asked, the signal been given by the admission of the Physical Sciences into the curriculum of our academical education? I trust that this question may be answered in the affirmative, if we are entitled to assume that the recognition of them which has already taken place will be constantly followed up by according to them some such substantial encouragement as that which has been afforded hitherto almost exclusively to classical literature. Our ability to accomplish this, with the means and appliances at our command, does not, I think, admit of dispute. All, therefore, that seems wanted, is, on the one hand, a more equal distribution of the existing emoluments between the several professions, and on the other, the admission of the claims of the sciences received into our educational system to share in the emoluments which up to this time, have been monopolized by the Classics. And, as it is far from my wish to curtail the older studies of the University of their proper share of support-fo: who that has passed through a course of academical study can be insensible of the advantages he has derived from that early discipline of the mind which flows from their cultivation ?--- I rejoice to think, that when the Legislature shall have completed the removal of those restrictions which have hitherto prevented us in many instances from consulting the claims of merit in the distribution of our emoluments, there will be ample means afforded for giving all needful encouragement to the newly-recognized studies, without trenching unduly upon that amount of pecuniary aid which has been hitherto accorded to the classics. In anticipation of which change, I look forward with confidence to the day when the requirements at Oxford in the department of Physical Sciences will become so general and so pressing, that no institution which professes to prepare the youth it instructs for academical competition will venture to risk its reputation by declining to admit these branches of study into its educational courses.

ON THE THEORY OF COMPOUND COLOURS WITH REFERENCE TO MIXTURES OF BLUE AND YELLOW LIGHT. BY MR. J. C. MAXWELL.

When we mix together blue and yellow paint, we obtain green paint. This fact is well known to all who have ever handled colours; and it is universally admitted that blue and yellow make green. Red, yellow, and blue being the primary colours among painters, green is regarded as a secondary colour, arising from the mixture of blue and yellow. Newton, however, found that the green of the spectrum was not the same thing as the mixture of two colours of the spectrum, for such a mixture could be separated by the prism, while the green of the spectrum resisted further decomposition. But still it was believed that yellow and blue would make a green, though not that of the spectrum. As far as I am aware, the first experiment on the subject is that of M. Plateau, who, before 1819, made a disc with alternate sectors of Prussian blue and gamboge, and observed that, when spinning, the resultant tint was not green, but a neutral grey, inclining

sometimes to yellow or blue, but never to green. Prof. J. D. Forbes, of Edinburgh, made similar experiments in 1849, with the same result. Prof. Helmholtz, of Königsberg, to whom we owe the most complete investigation on visible colour, has given the true explanation of this phenomenon. The result of mixing two coloured powders is not by any means the same as mixing the beams of light which flow from each separately. In the latter case we receive all the light which comes either from the one powder or the other. In the former, much of the light coming from one powder falls on a particle of the other, and we receive only that portion which has escaped absorption by one or other. Thus, the light coming from a mixture of blue and yellow powder, consists partly of light coming directly from blue particles or yellow particles, and partly of light acted on by both blue and yellow particles. This latter light is green, since the blue stops the red, yellow, and orange, and the yellow stops the blue and violet. I have made experiments on the mixture of blue and yellow light-by rapid rotation, by combined reflection and transmission, by viewing them out of a focus, in stripes, at a great distance, by throwing the colours of the spectrum on a screen, and by receiving them into the eye directly; and I have arranged a portable apparatus by which any one may see the result of this or any other mixture of the colours of the spectrum. In all these cases blue and yellow do not make green. I have also made experiments on the mixture of coloured powders. Those which I used principally were "mineral blue" (from copper) "and chrome yellow." Other blue and yellow pigments gave curious results, but it was more difficult to make the mixtures. and the greens were less uniform in tint. The mixtures of these colours were made by weight, and were painted on discs of paper, which were afterwards treated in the manner described in my paper 'On Colour as perceived by the Eye, in the Transactions of the Royal Society of Edinburgh, Vol. xxr., Part 2. The visible effect of the colour is estimated in terms of the standard coloured papers: -vermilion (V,) ultramarine (U,) and emerald green (E.) The accuracy of the results, and their significance, can be best understood by referring to the paper before mentioned. I shall denote mineral blue by B, and chrome yellow by Y; and B. Y<sub>5</sub> means a mixture of three parts blue and five parts yellow.

—The columns V, U., E. give the proportions of the stardard colours which are equivalent to 100 of the given colour; and the sum of V., U., E. gives a co-efficient, which gives a general idea of the brightness. It will be seen that the first admixture of yellow *diminishes* the brightness of the blue. The negative values of U. indicate that a mixture of V., U., and E. cannot be made equivalent to the given colour. The experiments from which these results were taken had the negative

values transferred to the other side of the equation. They were all made by means of the colour-top, and were verified by repetition at different times.

" ON SOME DICHROMATIC PHENOMENA AMONG SOLUTIONS, AND THE MEANS OF REPRESENT-ING THEM," BY DR. GLADSTONE.

This paper was an extension of Sir John Herschel's observations on dichromatism, that property whereby certain bodies appear of a different colour according to the quantity seen through. It depends generally on the less rapid absorption of the red ray as it penetrates a substance. A dichromatic solution was examined by placing it in a wedge-shaped glass-trough, held in such a position that a slit in a window-shutter was seen traversing the varying thicknesses of the liquid. The diversely coloured line of light thus produced was analyzed by a prism; and the resulting spectrum was represented in a diagram by means of coloured chalks on black paper, the true position of the apparent colours being determined by the fixed lines of the spectrum. In this way the citrate and comenamate of iron, sulphate of indigo, litmus in various conditions, cochineal, and chromium, and cobalt salts where examined and represented. Among the more notable results were the following :- A base, such as chromic oxide, produces very nearly the same spectral image with whatever acid it may be combined, although the salts may appear very different in colour to the unaided eye. Citrate of ircn appears green, brown, or red, according to the quantity seen through. It transmits the red ray most easily, then the orange, then the green, which covers the space usually occupied by the yellow; it cuts off entirely the more refrangible half of the spectrum. Neutral litmus appears blue or red, according to the strength or depth of the solution. Alkalies cause a great development of the blue ray; acids cause a like increase of the orange, while the minimum of luminosity is altered to a position much nearer the blue. Boracic acid causes a development of the violet. Alkaline litmus was exhibited so strong that it appeared red, and slightly acid litmus so dilute that it looked bluish purple; indeed, on account of the easy transmissibility of the orange ray through an acid solution, the apparent paradox was maintained that a large amount of alkaline litmus is of a purer red than acid litnus itself. Another kind of dichromatism was examined, dependent not on the actual quantity of coloured material, but on the relative proportion of the solvent. Diagrams of the changing appearances of sulphocyanide of iron, of chloride of copper, and of chloride of cobalt were exhibited.

"ON A METHOD OF DRAWING THE THEORETICAL FORMS OF FARADAY'S LINES OF FORCE WITHOUT CALCULATION," BY MR. J. C. MAXWELL.

The method applies more particularly to those cases in which the lines are entirely parallel to one plane, such as the lines of electric currents in a thin plate, or those round a system of parallel electric currents. In such cases, if we know the forms of the lines of force in any two cases, we may combine them by simple addition of the functions on which the equations of the lines depend. Thus the system of lines in a uniform magnetic field is a series of parallel straight lines at equal intervals, and that for an infinite straight electric current perpendicular to the paper is a series of concentric circles whose radii are in geometric progression. Having drawn then two sets of lines on two separate sheets of paper and laid a third piece above, draw a third set of lines through the intersections of the first and second sets. This will be the system of lines in a uniform field disturbed by an electric current. The most interesting cases are those of uniform fields dis-

#### AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE. 63

turbed by a small magnet. If we draw a circle of any diameter with the magnet for centre, and join those points in which the circle cuts the lines of force, the straight lines so drawn will be parallel and equi-distant, and it is easily shewn that they represent the actual lines of force in a paramagnetic, diamagnetic, or crystallized body, according to the nature of the original lines, the size of the circle, &c.

#### ON THE FORM OF LIGHTNING.

Mr. J. Nasmyth read a paper to the effect that the form of lightning as exhibited by nature was an irregular curved line, shooting from the earth below to the cloud above, and often continued from the cloud downwards again to some distant point of the earth; and this appearance was the result of the rapidly-shooting point of light, which constituted the true lightning, leaving on the eye the impression of the path it traced. These views led to much discussion in the Section.

(To be continued.)

#### AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

The Tenth Meeting of the American Association for the Advancement of Science was opened at Albany, in the Capitol of the State of New York, on the 20th of August, by Professor James B. Hall. A deputation from Montreal was introduced to the association on the following day, and Principal Dawson of McGill College, in the name of the deputation, communicated the invitation to the Association,—which at a subsequent meeting was accepted,—that the next meeting should be held in Montreal.

The American Association is still on a much smaller scale than its British prototype; and in some respects presents characteristic differences. The arrangements of business, which are left in the British Association exclusively in the hands of the Central Committee, were at Albany repeatedly made the subject of discussion by the whole body; and a good deal of time was lost in debates in general meeting, upon questions of order and constitutional forms, little calculated to interest those who had been attracted from a distance by the desire to listen to the communications of the distinguished representatives of American Science assembled on the occasion. Another characteristic, which could scarcely fail to strike those who are familiar with the proceedings of the British Association, was the absence of that numerous body of youthful aspirants for a place among the ranks of the Scientific Legion, which constitutes so valuable a feature in the Sections at Home. Already, chairs in the Colleges of England, Scotland, and Ireland, are filled by those who owed their first introduction to the Scientific world to the Sections of the British Association; and not the least of the benefits traceable to that institution pertain to this important feature of its organization, which has been so employed as to invite the younger students of Science into the arena, and stimulate them to compete with those whose rank has long been established by universal consent. The American Association on the contrary seems chiefly composed of the veterans of Science; nor was there wanting some appearance of an apprehension of any greater infusion of the popular element, such as the influence of the political institutions of that Country on all large and some-

### 64 AMEEICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

what miscellaneous assemblies may perhaps fully justify. But whatever may be the effects of this absence of the predominating element of youthful aspirants for honors in the field of Scientific adventure, the assembly of so many of the most distinguished representatives of American Scientific Veterans, was a peculiarly acceptable feature to those who were allured from other countries, by the echo of their fame. Nor must it be overlooked that in whatever other respects the popular element may work, it is scarcely possible for a warmer or more hospitable welcome to be offered any where, than that which the citizens of Albany, and the Official representatives of the State of New York, tendered to the assembled Congress of American Science, and to the visitors attracted by the justly earned reputation of its members.

The great feature of interest at this meeting was the inauguration of the Dudley Astronomical Observatory. This observatory has been founded by the liberality of some citizens of Albany, among whom Mrs. Dudley, whose name it bears, has not only contributed upwards of \$25,000 for the building and instruments but has announced a further donation of \$50,000 towards its permanent endowment. The Hon. Edward Everett delivered a splendid oration on the occasion, in the presence of the Association, the dignitaries of the State, and the citizens of Albany, the venerable foundress herself occupying the seat of honour. The observatory is built in a solid and massive style, and finely situated on the brow of a hill; its erection was superintended by a committee of eminent astronomers, and the construction of the instruments was entrusted to Dr. Gould, who has accepted the appointment of Director. At a meeting in Section, Dr. GOULD described in detail the new instruments. The minor instruments have been received, and the Observatory has been fitted up with these and others lent by Prof. BACHE from the Coast Survey, but the reception of the larger instruments will be delayed for a few weeks longer. The Transit circle, combining in one the Transit telescope and meridian circle, was ordered from PISTOR and MARTIUS, the celebrated manufacturers of Berlin, by whom the new instrument at Ann Arbor was made. A number of improvements have been introduced in the Albany instruments, not perhaps all absolutely new, but an eclectic combination of late adaptations with new improvements. Dr. GOULD made a distinction of modern astronomical intruments into two classes, the English and the German. The English is the massive type; the German, light and airy. The English instrument is the instrument of the engineer; the German, the instrument of the artist. In ordering the instruments for the Albany Observatory, the Doctor had endeavoured to combine the two, with, however, a preference to the German type. The circle is three feet in diameter, graduated to intervals of two minutes, and read by micrometers to tenths of seconds. The microscopes are four in number, and are not carried by moveable frames, but are imbedded in the piers. The piers themselves completely surround the circle so as to eliminate the effect of changes of temperature by radiation. The tube of the telescope is eight feet in length, and the object glass is eight inches clear aperture. The glass was made by Chance, of Birmingham, and ground by Pistor himself. The eye-piece, in addition to the diaphragm, is furnished with two micrometers, one for vertical, the other for horizontal motion, the use of these being for the circumpolar stars, whose motion is too slow for registration by the Chronographic method. One principle has been adhered to in the whole of the instrumental arrangements, namely: that every error is capable of being determined in two independent ways.

## AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE. 65

Much trouble was experienced in securing a good casting for the steel axis of the instrument. Three were found imperfect under the lathe, and the fourth was chosen, but even then, the pivots were made in separate pieces, which were set in very deeply, and welded.

Dr. GOULD said he would have preferred a smaller instrument, in which the facilities of manipulation would have been greater, but was hampered by one proviso, upon which the Trustees of the institution insisted—that this should be the biggest instrument of its kind, and the instruction was obeyed. He had been requested by the gentlemen who had this enterprise in charge, to suggest, as a mark of respect to a gentleman of Albany, who was a munificent patron. of Science, that this instrument be known as the Olcott Meridian Circle. The other large instrument for the Observatory, the Heliometer, has been entrusted to an American artist, but is not yet completed. It was also announced that the American Astronomical Journal, hitherto supported at Dr. Gould's editorship, the responsibility of its cost having been assumed by a number of gentlemen of that City.

Among the Astronomical papers read before the Association was one by Dr. PETERS on a Periodical Comet of thirteen years. This Comet was discovered by Dr. PETERS, at Naples, in 1846. He has prepared an ephemeris of the Comet from 1857 to 1860. The comet was very difficult to observe; its light was so faint in 1846 that he could not perceive it until he had reposed his eye for some seconds in darkness. Even under these circumstances he had only seen it at intervals during a period of twenty days. He had devoted some time to calculating where the comet might be looked for on its re-appearance, and had drawn lines on a map, from eight days to eight days, so that the observer would be saved much of the labor of sweeping, and the comet could readily be discovered. The probable orbit gives an ellipse of thirteen years, with a probable error of one year, so that its period might be twelve or fourteen years. In 1854, Saturn came into nearly the same position as this comet, and some uncertainty exists as to its distance, it having been difficult to ascertain whether it was nearer the interior or the exterior of that planet. Unless some accident had happened, the comet might be looked for either fifty-six days before or fifty-six days after the 15th of March, 1859. This enquiry had become of more importance since two comets pronounced periodic, those of de Vico and Brünnow, had failed to re-appear. Dr. PETERS remarked that the discovery of comets has decreased. Last year, not more than one or two were discovered. He thought this falling-off is owing partly to the fact that the award of a comet medal has been abandoned by the King of Denmark. For many years, the discoverer of any telescopic comet received a comet-medal from the King, but in 1848 the custom was abolished, and the zeal for discovery has since declined. He hoped the institution of the comet-medal would be renewed here.

Dr. GOULD observed that it was not a little curious that since the establishment of the Observatory at Pultowa the realm of Denmark had contributed 200 per cent. more to the progress of astronomical science, in proportion to its population, than any other country. The comet medal, whose institution was suggested by Schumacher, continued to be awarded for fifteen years, during which period the discoveries of comets averaged five to seven per annum, and the average discover-

#### 66 AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIECE.

ies of each comet by independent observers three to four. Since it has been abolished the discoveries of comets have not averaged over three per annum, and the independent simultaneous discoveries of the same comet have become exceedingly rare.

### THE UNITED STATES COAST SURVEY.

The progress of this magnificent work has furnished, as usual, many valuable results in Science since the preceding meeting of the Association; the following abstracts of the Papers read will shew how great credit is due both to the energy and skill of the conductors of this undertaking, and to the wise liberality of the Government which supports it.

"The Distribution of Terrestrial Magnetism in the United States," by Prof. Bache and J. D. Hilgard.

The magnetic observations made in connection with the Survey were scattered, at 160 different stations, along the entire sea coast, and the data were reduced to the common period of the year 1850. The line of no variation, or that passing through all the places where the magnetic needle points to the true north, intersects the coast near Ocracoke, between Cape Hatteras and Cape Fear, in a N.N.W. direction, curving gradually to the North, and passing through the middle of Lake Erie.

To the north and east of this line the declination (or variation of the compass) is to the west of north, being 6° near New York,  $10^{\circ}$  near Boston, and  $16^{\circ}$  in the eastern part of Maine. To the south and west of the line of no variation it is east of north, being 8° east along a line running directly south a little to the west of St. Louis and New Orleans,  $13^{\circ}$  near San Diego, and  $21^{\circ}$  near Cape Flattery on the western coast. The dip of the needle varies from  $75^{\circ}$  in the North eastern States to  $60^{\circ}$  along the northern shore of the Gulf of Mexico, and the horizontal force from 3.5 to 6.0 in the same regions.

SUPPLEMENT TO THE PAPER PUBLISHED IN THE PROVIDENCE PROCEEDINGS, ON THE SECULAE VARIATION IN MAGNETIC DECLINATION IN THE ATLANTIC AND GULF COAST OF THE UNITED STATES, FROM OBSERVATIONS IN THE SEVENTEENTH, EIGHTEENTH AND NINETEENTH CENTURIES, UNDER PERMISSION OF THE SUPERINTENDENT. BY CHAS. A. SCHOTT.

In a paper communicated to the Association at the Providence meeting the secular change of the magnetic declination was investigated by Mr. Schott. In the course of last summer he made some additional observations by direction of the Superintendent of the Coast Survey, and in the paper now presented the results are combined with those previously obtained. The former deductions have gained considerably in accuracy, and have received important additions. The number of stations is increased from ten to thirteen. The recent observations appear to show a slight diminution in the rate of increase of westerly declination, leading to the supposition that the inflexion in the curve representing the secular variation corresponds to about 1850. All the observations concur in placing the minimum about 1800. The present rate of increase of westerly declination is about five minutes annually along the Atlantic coast.

DISCUSSION OF THE SECULAR VARIATION OF MAGNETIC INCLINATION IN THE NORTH-EASTEEN STATES. COMMUNICATED, UNDER PERMISSION OF THE SUPERINTENDENT AND AUTHORITY OF THE TREASURY DEPARTMENT, BY CHARLES A. SCHOTT.

The results are confined to the limits of 38 deg, and 44 deg, of North latitude, there being too few observations in the southern part of the United States to permit
safe inferences there. The element of magnetic dip, though less important practically than that of declination, is of value in navigation in certain latitudes, and from its connection, through Gauss' investigations, with the declination and intensity, assumes a high degree of importance. While the declination observations on this coast go back to the seventeenth century, the dip has only been accurately observed for 23 years; for the earliest observations made in 1782 were, from the imperfection of the instruments, of little value. During this period the dip has decreased, reached a minimum, and begun again to increase, so that it has been a highly interesting period for observation. The lines of equal dip have been deduced by Professor Loomis, from the observations which he had accumulated before the date of his paper. The present memoir includes additional results, and discusses 161 observations made at the different stations between Toronto on the north, and Baltimore on the south. The average probable error of the result at any one station is about one minute and six-tenths of dip, and the time of minimum dip is ascertained to be about two years and seven-tenths. This time was the year 1843, or rather the close of 1842 (1842-7). Mr. Schott points out why these results do not agree with Professor Hansteen's, who had not observations enough to determine the epoch of minimum dip with accuracy. Observations on the Western coast confirm these results for the Eastern.

ON THE CAUSE OF THE INCREASE OF SANDY HOOK. BY PROF. BACHE.

It is well known, as one of the developments of the Survey, that the Hook is gradually increasing, growing to the northward into the main ship channel. At a spot north of the Hook, where there were forty feet of water when Captain GEDNEY made his survey, in less than ten years it was nearly bare. The importance of determining the cause of this increase, as leading to the means of controlling it cannot be over estimated. The Commissioners on Harbor Encroachments had early attended to the matter and requested that the necessary observations for its investigation should be made. These were under the immediate direction of Prof-BACHE, the observations having been made by HENRY MITCHELL, one of the sub-assistants in the Coast Survey, with all desirable zeal and ability.

Various causes had been assigned for this growth from the action of the waves and the winds, sometimes on the outer side and sometimes on the inside of the Hook. The effect of the opening and closing of Shrewsbury inlet had also been insisted upon.

To examine these and other probable causes laborious observations of tides and currents had been made in the vicinity of stations which Prof. BACHE showed upon the map. Careful measurements of the low water line had also been made in connection with these observations, and with others of the force and direction of the winds. Objects easily distinguished from the sand, and of various specific gravities and shapes, had been deposited near the shore of the Hook to determine the power and direction of transportation of matter along the shores of the Hook. The results of these observations have not yet been worked out in all their detail, but the conclusions from them are perfectly safe, and are of the highest importance. Itturns out that this growth of the Hook is not an accidental phenomenon, but goes on regularly and according to determinable laws. The amount of increase depends upon variable causes, but the general fact is that it increases year by year, and the cause of this is a remarkable northwardly current, the amount and duration of which these observations assign along both shores of the Hook, the outer one extending across the whole breadth of False Hook channel, with varying velocity, and the one

inside of the Hook extending nearly one-third of the distance across Sandy Hook Bay. These currents run to the north, during both the ebb and flood tide, with varying rates, and result from those tides directly and indirectly. The inner current is the one by which the flood and ebb tides draw, by the lateral communication of motion, the water from Sandy Hook Bay, and the outer is similarly related to those tides as they pass False Hook channel. The velocities and directions found, favor this conclusively.

An important observation for navigation results from this, for eleven hours out of the twelve, there is a northwardly current running through False Hook channel, which assists vessels entering New York harbor on the ebb tide, and is to be avoided in passing out with the ebb.

It is the conflict of these two northwardly currents outside and inside, and the deposit of the materials which they carry to the point of the Hook, which causes its growth.

Within a century it has increased a mile and a quarter, and at about the rate of one sixteenth of a mile a year, on the average, for the last twelve years.

Flynn's Knoll, on the north side of the main ship channel, does not give way, as the point of the Hook advances. The importance of watching this movement cannot, therefore be over stated.

The mode of controlling the growth is obvious from the result obtained. The observations are still continued, to obtain the necessary numerical results.

APPROXIMATE COTIDAL LINES OF DIURNAL AND SEMI-DIURNAL TIDES OF THE COAST OF THE UNITED STATES ON THE GULF OF MEXICO-BY A. D. BACHE, SUPERINTENDENT UNITED STATES COAST SURVEY. COMMUNICATED BY AUTHORITY OF THE TREASURY DEPART-MENT.

This paper is supplementary to those on cotidal lines of the Atlantic and Pacific coasts heretofore communicated to the Association. Preparation was made at the last meeting for these conclusions by presenting the type curves of the Gulf coast The tides from Cape Florida to St. George's are of the usual type, with a large daily inequality. From St. George's to the mouth of the Mississippi they are of the single day type. Then the half-day tides reappear to extend beyond Galveston, the day tides recurring at Aransas, in Texas, and southward. When the type curves were presented, the mode of decomposing them with a diurnal and semi-diurnal wave was described. The tide stations extend along our whole coast, but observations are much wanted beyond it to complete the investigation, on the south side of the Straits of Florida, on the eastern coast of the Gulf of Mexico south of Texas, and especially between Cuba and Yucatan, at the entrance of the Gulf from the Caribbean sea.

A table of the stations at which the observations were made, of the heights of tide (rise and fall) observed, and of the half-day and day tides, was given; and another showing the period of observation and the name of the observer. The first table is represented on a diagram by which a navigator may find the rise and fall of tide approximately on any part of our Gulf coast. The least observed rise and fall is at Brazos Santiago, Texas, and is nine tenths of a foot. The greatest is at Cedar keys, Florida, and is two and a half feet. The difficulties of the problem presented by these tides are explained, removable in part by the progress of the survey of the Gulf, inherent in them in part. The labors of Mr. Pourtales and other gentlemen concerned in the discussion of these tides are acknowledged. The single-day tides have not been so elaborately discussed by former physicists or mathe-

maticians as to prepare the way fully for this work. The formula for the times given by Professor Avery in his "Tides and Waves," when compared with the observed times, differs remarkably in certain parts of the lunar month. A diagram shows the general form of the curve of interval between the moon's transit and high water. Advantage is taken of the part of the curve which changes but little in ordinate to obtain an average luni-tidal interval corresponding in kind with the number for semi-diurnal tides, known at the establishment. These tides occur about the period of greatest declination of the moon. These intervals, at greatest declination, vary greatly during the year; and the form of curve showing the annual change is presented, as deduced from observations at key West, Fort Morgan (Mobile entrance), and Galveston, as well as from San Francisco, on the Western coast, where the results are remarkably regular. These annual curves are used to deduce the average number for the interval of the daily tides from the short series of observations; the limits of uncertainty of the process are pointed out. These intervals are next turned into cotidal hours by the usual process of correcting for the difference of longitude, for transit, for depth, and by the process just described for the annual change. A table of cotidal hours for the various stations is then given. By it the cotidal lines are traced, the tide waves entering the Straits of Florida, passing through them, crossing to the entrance of the Mississippi, and passing laterally to the western coast of the peninsula of Florida from south to north, and along the southern coast of Upper Florida, along the eastern coast of Louisiana from the Southwest Pass northward, and along the coast of Mississippi. Also, into the Gulf between Southwest pass and the Rio Grande, in such a way that Galveston has, as the head of the Gulf, the latest cotidal hour. By forming groups of stations, the direction of the cotidal lines, the mean cotidal hour, and the velocity of the wave's movement are roughly determined. The difficulties of forming the groups are explained, and the general character of the results given by them are shown in a table and upon a diagram map. Upon the map also are given the cotidal hours of the stations, and the results of the grouping. Finally, from the study of the groups and their connection, the cotidal lines or the daily tides are drawn upon the map. The main cotidal hour of the northern shore of the Gulf is twenty-six hours, twenty seven occurring at the head of the bight in which Galveston lies. The twenty-five hour line appears at Cedar Keys, and touches the coast again at Brazos Santiago. Twenty-three is at the Tortugas and Key West, and nineteen at Cape Florida.

A similar course to that just described is followed in the discussion of the semi-diurnal tides. The table of stations, their positions, and the other data necessary to obtain cotidal hours is given. The progress of the semi-diurnal wave as indicated by three hours is also shown. The general motion of the wave is like that of the diurnal wave, with very characteristic peculiarities. From the line of deep water joining the Tortugas and Southwest Pass at the entrance of the Mississipi the semi-diurnal wave reaches the stations on the western coast of the Florida peninsula in this order, from south to north and west. The movement west of St. George's appears to be in the order of Pensacola, Fort Morgan and Cat Island, while for the diurnal wave is a sudden increase of establishment, as if another semi-diurnal wave brought the tides there. The mean cotidal hour of the five sections west of Southwest Pass is 20 h. 6 m., while that of Southwest Pass and three east of it is 16 h. 17 m., a difference of about four hours. This taken with

the remarks already made in regard to the appearance of two high waters in the curves for Isle Dernier and Calcasieu, indicate a system of interferences yet to be unrayelled. As was the case with the diurnal wave, the stations at Isle Dernier and Calcasieu gave cotidal hours very like those of Brazos Santiago and Aransas, and Galveston is later then either.

The differences between the cotidal hours for the diurnal and semi-diurnal tides are shown in a table. The grouping of the semi-diurnal results is next made, and the results tabulated and drawn on a diagram map. This map also shows the cotidal lines deduced. The cotidal lines of thirteen and fourteen hours only appear on the coast of the Florida Keys; that of sixteen hours is well marked, near Egmont Key (Tampa), and passes around the shore of the great Bay, between Louisiana and Florida, to near Southwest Pass. The line of eighteen hours is at the head of the heights, between St. George's and Cedar keys, and seventeen in that near Cat Island; the lines of sixteen and twenty-one have succeeded each other closely in the bay to the westward of Southwest Pass.

In comparing the two sets of cotidal lines for the diurnal and semi-diurnal waves, we find a general resemblance in the great bay between the western coast of Florida and the eastern coast of Louisiana. The lines of 24, 25 and 26 of the diurnal tide on the eastern side of the bay, corresponding generally with 16, 17 and 18 of the semi-diurnal tides and 25 and 26 hours of the diurnal tide on the western side of the bay corresponding generally to 16 and 17 of the semi-diurnal. On the southern coast of Florida, by the Keys, on the contrary the lines of 19, 20, 21, 22 and 23 hours succeed each other rapidly between Cape Florida and the Tortugas, in the diurnal series, along the same shores in the semi-diurnal tide. On the contrary on the west of southwest Pass, the lines of 26, 27 and 28 hours only occur at considerable distances in the diurnal system, while 16, 17, 18, 19, 20 and 21 occur in the same space between Southwest Pass and Brazos Santiago in the same diurnal tide-

### NOTES ON THE PROGRESS MADE IN THE COAST SURVEY, IN PREDICTION TABLES FOR THE TIDES OF THE UNITED STATES COAST, BY A. D. BACHE, SUPTD., ETC.

Communicated by authority of the Treasury Dept.

As soon as tidal observations had accumulated sufficiently to make the task a profitable one, I caused them to be treated, under my immediate direction, by the methods in most general acceptance. The observations at Old Point Comfort, Virginia, were among the earliest used for this purpose, and the labors of Commander Charles H. Davis, U. S. N., then an assistant in the coast survey, were directed to their reduction chiefly by the graphical methods pointed out by Mr. Whewell. This work was subsequently continued by Mr. Lubbock's method, by Mr. Henry Mitchell; and next the tides of Boston harbor were taken up as affording certain advantages in the observations themselves, which could not be claimed for those of Old Point.

The system of Mr. Lubbock is founded on the equilibrium theory, and in it the inequalities are sought by arranging the elements of the moon's and sun's motions, upon which they depend. Having obtained the coefficient of the half monthly inequality of the semi-diurnal tide at Boston, from seven years' observations, through the labors of the tidal division, and approximate corrections for the parallax and declination. I was much disappointed in attempting the verification by applying to individual tides for a year during which we had observations. There was a general agreement on the average but a discrepancy in the single cases, which was quite

unsatisfactory. Nor were these discrepancies without law, as representing their residuals by curves did not fail to show. By introducting corrections for declination and parallax of the moon increasing and decreasing, we reduced these discrepancies, but still the results were not sufficient approximations. With the numerical reductions of the observations before referred to, was commenced in 1853, under my immediate direction, by Mr. L. W. Meech, a study of the theory of the tides, directed chieffv to the works of Bernoulli, La Place, Avery, Lubbock and Whewell. The immediate object which I had in view was the application of the wave theory to the discussion of our observations. I thought that the mind of an expert mathematician, directed entirely to the theoretical portions of this work, with directionby a physicist, and full opportunities of verifying results by extended series of observations, the computations of which should be placed by others in any desired form, would give, probably, the best result in this combined physical and mathematical investigation.

The general form of the different functions expressing the tidal inequalities is the same in the different theories, and may be said on the average to be satisfactory as to the laws of change which these inequalities present. Whether we adopt, with La Place, the idea that periodical forces produce periodical effects, or with Avery, that the tidal wave arrives by two or more cauals; or with Bernoulli and Lubbock, the results of an equilibrium spheroid; or with Whewell, make a series of inequalities, semi-menstrual, parallax and declination, with different epochs, we arrive at the same general results, that the heights and times of high water may be represented by certain functions, with indeterminate co-efficients, in the form of which the theories in a general way agree. By forming equations from the observations, and obtaining the numerical values of the co-efficients by the methods used so commonly in astronomical computations, the result is accomplished.

A general consideration of the co-ordinates in space of the moon and sun, without any special theory, would lead to the same result, representing the luni-tidal interval by a series of sines and co-sines, with indeterminate co-efficients.

The grouping of the observations of one year at Boston, to apply this methodthe formation of the equations and their solution by the method of indirect elimination has been the work of Mr. R. L. Avery.

To test the co-efficients, computations, for the predicted times of the tide at Boston harbor were made for a period from March 1853, to January 1854, and from comparison of these with the observed, it appears that in twenty pairs of tides, the morning and afternoon being grouped to get rid of the diurnal inequality, there are two differences of less than two 2 m., thirteen of more than 2 m. and less than 4 m., three of more than 4 m. and less than 10 m., two of more than 10 m. The probable error of the prediction of a single pair of tides is 4.12 m. so that greater accuracy of prediction has been attained by this method from a single years's observations that was found at London bridge from a period of nineteen years.

#### LAW OF MORTALITY.

Prof. McCoy, of Albany, read a paper in which he announced the important discovery of a mathematical formula which correctly expressed the law of mortality for all ages; it was first evolved from an analysis of the Carlisle and Northampton tables, but the Professor had compared it with a large number of others and said that, "so complete is its agreement with all, that at no age does the calculated number of the living differ from the number given in the tables by a single year's mortality." The formula is, that, for the age x, the rate of mortality or the ratio of the dead to the living for that age is expressed by

ab<sup>x</sup>

where, a, b, c, are constants which differ for different tables. From this the Professor drew the following conclusions;

1. The rate of mortality invariably increases from youth to old age.

2. This rate is continually accelerated even in a higher ratio than in geometrical progression.

3. In early manhood, the rate does not differ much from a slow arithmetical progression.

4. There are no crises or climacterics at which the chances for life are stationary or improving.

5. There are no periods of slow and rapid increase succeeding each other; but one steady, invariable progress.

6. The law, though not the rate of mortality, is the same for city and country, for healthy and unhealthy places, for every age and country and locality; and this law is that the differences of the logarithms of the rates of mortality are in geometrical progression.

#### OZONE OBSERVATION.

Prof. Rogers gave an account of some observations made by him on the existence of ozone in the atmosphere. In the first instance these were made at Boston, and he here found winds blowing from the sea heavily ozonised, while those from the land were less so; on removing, however, fifty miles inland, he found the indications of ozone apparently independent of the quarter from which the wind was blowing, and depending more on its velocity; in a calm there being but slight ozonic effect, the increase being marked with the violence of the wind. This was to have been expected from the imperfect character of the mode of observation, since the effect produced on the test paper would depend on the quantity of ozone brought in contact with it, and this of course depended on the quantity of air that passed over it in a given time. To remedy this defect, he had arranged an apparatus by which the number of cubic feet of air passing over the test paper could be measured.

Dr. Webster, of Norfolk, added an important observation, "Last year, while the yellow fever was at Norfolk and Portsmouth, I kept an ozonometer constantly exposed to the air, and never detected ozone. This year I have used the ozonometer in the same place, and at the same period of time, and I find ozone in abundance."

THERMIC EFFECT OF THE SUN'S RAYS.

In a paper, by Mrs. Eunice Foote, some interesting results of experiments on this subject were given. The experiments were made by exposing freely to the Sun's rays a thermometer, with blackened bulb, enclosed in a glass receiver, which contained the various gases experimented on. The effect was found to be greatest of all in Carbonic Acid gas: for example, when in air the thermometer stood at 106°, in Hydrogen it stood at 104°; in Oxygen, at 108°, and in Carbonic Acid at 125°. It was also found that the thermic effect was increased in air by an increase of its density and also by an increase of the moisture in it.

(To be continued.)

MONTHLY METEOROLOGICAL REGISTER AT THE PROVINCIAL MAGNETICAL OBSERVATORY, TORONTO, CANADA WEST, OCTOBER, 1856.

| Amount of Evaporation 2.17 inches                                                                                                                      |
| Rain fell on 10 days, amounting to 5.220 inches; it was raining 50 hours and 5 minutes.                                                                |
| Most prevalent wind, W S W. Least prevalent wind, E by S.                                                                                              |
| Most windy day, the 29th day; mean miles per hour, 16.55.                                                                                              |
| Least windy day, the 5th day, mean miles per hour, 0.23                                                                                                |
| Most windy hour, from 10 to 11, A. M., 29th day; velocity 31.00 miles.                                                                                 |
| There were 226 hours and 45 minutes calm.                                                                                                              |
| There were 9 cloudless days in the month.                                                                                                              |
|                                                                                                                                                        |

Total amount of miles of wind, 3732.10 miles, which being resolved into the Four Cardina Points, gives N 843 miles, S 371 miles, W 2270.10 miles, and E 248 miles.

Aurora Borealis visible on 5 nights.

Eclipse of the Moon on the 13th day visible.

The electric state of the atmosphere has been marked by moderate intensity.

Ozone was in moderate quantity.

Rain fell on 8 days, amounting to 6.999 inches; it was raining 31 hours.

Snow fell on 7 days, amounting to 5 inches; it was snowing 19 hours 30 minutes.

Most prevalent Wind was WNW-.1064 miles.

Least prevalent Wind was NNE-.1 mile.

Most windy day, the 5th; mean miles per hour, 26.62.

Least windy day, the 12th; mean miles per hour, 0.05.

Most windy hour from 3 to 4 a. m., on the 8th, 36.40 miles.

There were 149 hours calm during the month.

There were 3 days cloudless.

The whole distance traversed by the wind was 4644 miles; resolved into the Four Cardinal Points, gives N 653; S 650; W 2386; E 975 miles.

Aurora Borcais visible on 2 nights.

The Zodiacal Light first seen on the 19th day, and was very bright on the 20th day.

A Rainbow was visible on the morning of the 7th, at 7.30 which was followed by Rain-Snow Birds first seen on the 26th day.

The electrical state of the Atmosphere has been marked by very moderate intensity. Ozone was in moderate quantity.

#### MEAN RESULTS OF METEOROLOGICAL OBSERVATIONS AT HAMILTON, C. W., FOR THE YEAR 1856.

| MONTHS. $\ddot{x}$ | 1856.                                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                                                                                           |                                                                                                                                                                                                                                     |                                                                                                                        |

#### TO THE READER.

"So numerous a body as the Canadian Institute now is, ought to include a much greater number of working members; and the Council are led to believe that their apparent supineness arises, in part at least, from the mistaken idea that communications can only be made in the form of elaborate essays. They would strongly urge the encouragement of brief communications, in greater number, as at once more calculated to give general interest to the ordinary meetings, and to elicit such results of personal knowledge and observation as are best calculated to add to the true value of the published proceedings.

"Short notices of natural phenomena, features of local geology, objects of natural history, and the like subjects, derived from personal observation, must be readily producible by many members who have hitherto borne no active part in the Society's proceedings, but whose contributions would most effectually promote the objects which it is designed to accomplish."

Extract from the Annual Report of 1855.

## THE DECREASE, RESTORATION, AND PRESERVATION OF SALMON IN CANADA.

BY THE REV. WILLIAM AGAR ADAMSON, D.C.L.

Read before the Canadian Institute, December 6th, 1856.

Brillat Savarin, in his "Physiologie du Gout," asserts that the man who discovers a new dish does more for the happiness of the human race than he who discovered the Georgium Sidus. If this be true, then he who could devise means for the preservation and increase of an old, wholesome and highly coveted article of food would not labor in vain, nor would, I imagine, his endeavors be despised by the members of the Canadian Institute, however humble his abilities, and however unskilled he might be in scientific lore. Actuated by this belief, as well as desirous to respond to the demand for co-operation among the members of the Canadian Institute, I would venture to lay before you some notes upon the decrease, restoration, and preservation of the Salmon (Salmo Salar) in Canada.

It is unnecessary to magnify the importance of this fish as an economic production, or as an article of commerce. As food it is beyond comparison the most valuable of fresh water fish, both on account of the delicacy of its flavor, and the numbers in which it can be supplied. By prudence, a little exertion, and a very small expense now, it may not only be rendered cheap and accessible to almost every family in Canada, but also an article of no small commercial importance as an export to the United States, in which country, by

VOL. II.-A

pursuing the course which Canada has hitherto imitated, this noble fish has been almost exterminated. Twenty-five or thirty years ago every stream tributary to the St. Lawrence, from Niagara to Labrador on the north side, and to Gaspé basin on the south, abounded with salmon. At the present moment, with the exception of a few in the Jacques Cartier, there is not one to be found in any river between the Falls of Niagara and the city of Quebec. This deplorable decrease in a natural production of great value has arisen from two causes ; 1st .- the natural disposition of uncivilized man to destroy at all times and at all seasons whatever has life and is fit for food; and 2nd.-the neglect of those persons who have constructed mill-dams, to attach to them slides, or chutes, by ascending which the fish could pass onwards to their spawning beds in the interior. It is supposed by many that the dust from the sawmills getting into the gills of the salmon prevents them from respirating freely, and so banishes them from the streams on which such mills are situated, but I am persuaded that this is a mistake, for salmon are found in considerable numbers at the mouths of many such streams, below the dams. In the Marguerite, in the Saguenay, at the Petit Saguenays, the Es-quemain, Port Neuf. Rimouski, Metis, and others that might be named, the real cause of the decrease is the insuperable obstacles presented by mill-dams, which prevent them from ascending to the ærated waters, high up the streams, which are essential for the fecundation of their ova, and so for the propagation of the species. Would you then-it may be asked, pull down our mills in order that we might have salmon in our rivers ? most certainly not, I reply, for it is quite possible to maintain all our mills, with all their mill-dams, and yet afford to the fish an easy and inexpensive mode of passing upwards to their breeding places.

Marvellous stories are told of the great heights which salmon will leap in order to surmount the obstacles which nature or art may have erected between the lower parts of a stream and the upper waters which are suited to breeding purposes. Natural historians used gravely to tell us that salmon, in order to jump high, were in the habit of placing their tails in their mouths, and then, bending themselves like a bow, bound out of the water to a considerable distance, from twelve to twenty feet. The late Mr. Scrope, in his beautiful book "Days and Nights of Salmon Fishing," calculates that six feet in height is more than the average spring of salmon, though he conceives that very large fish in deep water, could leap much higher. He says, "Large fish can leap much higher than small ones; but

their powers are limited or augmented according to the depth of water they spring from; in shallow water they have little power of ascension, in deep they have the most considerable. They rise very rapidly from the very bottom to the surface of the water by means of rowing and sculling as it were, with their fins and tail, and this powerful impetus bears them upwards in the air, on the same principle that a few tugs of the oar make a boat shoot onwards after one has ceased to row." However this may be, we know that salmon use almost incredible efforts to ascend their native rivers. Modes have recently been adopted in France, in England, Scotland and Ireland, by which they can do so with ease, and which can be much more cheaply applied to Mill-dams in Canada, than in any of the countries above mentioned. This is simply by constructing below each milldam a congeries of wooden boxes proportioned to the height of the dam-which could be done, in any weirs I have seen requiring them, for a sum not exceeding twenty dollars. We will suppose that the mill-dam to be passed over is fifteen feet high from the surface of the water, and that the salmon can surmount the height of five feet at a single bound, then it would be only necessary to erect two boxes, each five feet high, one over the other (as in the illustration) to enable the salmon, in three leaps, to reach the waters which nature prompts him to seek for the propagation of his species. In many Canadian rivers-such as Metis, Matane, Rimouski, Trois Saumons, etc .- this simple apparatus might be put in operation for one half the sum I have mentioned, and I trust it has only to be suggested to the gentlemen residing on their banks to arouse their patriotism and excite them to activity in the matter. There can be no doubt that were the milldams removed, or boxes constructed adjacent to them, and protection afforded to the spawning fish, many of the rivers in Upper Canada would again abound with Salmon. I have myself, within a few years, taken the true Salmo Salar in Lake Ontario, near Kingston, and many persons in Toronto know that they are taken annually at the mouths of the Credit, the Humber and at Bond Head, in the months of May and June, which is earlier than they are generally killed below Quebec. Whether these fish come up the St. Lawrence in the early spring, under the pavement of ice which then rests upon its surface, or whether they have spent the winter in Lake Ontario, is a question which I must leave to naturalists; merely mentioning that there is some foundation for believing that salmon will not only live. but breed, in fresh water, without visiting the sea. Mr. Lloyd, in his interesting work on the field sports of the North of Europe, says,

"Near Katrineberg, there is a valuable fishery for salmon, ten or twelve thousand of these fish being taken annually. These salmon are bred in a lake, and, in consequence of cataracts, cannot have access to the sea. They are small in size and inferior in flavor," which may also be asserted of salmon taken in the neighborhood of Toronto. Mr. Scrope, in his work previously quoted, states that Mr. George Dormer, of Stone Mills, in the Parish of Bridport, put a female of the salmon tribe, which measured twenty inches in length, and was caught by him at his mill-dam, into a small well, where it remained twelve years, became quite tame and familiar, so as to feed from the hand, and was visited by many persons of respectability from Exeter and its neighborhood.

But the fact that salmon are annually taken near the Credit, the Humber and Bond Head is sufficient ground on which to base my argument for the probability that were the tributary streams of the St. Lawrence accessible to them they would ascend and again stock them with a numerous progeny. Even were this found not to be the case,-then we have the system of artificial propagation to fall back upon-a system which according to the Parliamentary Reports of the Fishery Commissioners has been practised with immense success in different parts of Ireland-according to M. Coste, Member of the Institute, and professor of the college of France, in his reports to the French Academy and the French Government, has answered admirably in France, and according to Mr. W. H. Fry and others, quoted by him in his treatise on artificial fish-breeding, has been generally effective in Scotland. This system, as is well known, consists simply of transporting from one river to another the impregnated eggs of the salmon, and placing them in shallow waters with a gentle current where they are soon hatched, and become salmon fry or par and able to take care of themselves. In consequence of the ova of the salmon, which are deposited in the spawning beds in the months of October. November and December, becoming congealed by frost in . the subsequent months, Canada appears to offer greater facilities for their safe transport than those countries in which the system has been so successful, but whose climates are more temperate. Surely, supposing this is a mere untried experiment-which is far from being the case-it would be well worth the while of some of the many wealthy and intelligent dwellers upon the banks of our beautiful rivers to test its value, particularly when they call to mind the well known fact in the natural history of the salmon, that he invariably returns to the stream in which his youth was spent, and that so they may calculate

upon having their present barren rivers stocked with as valuable articles of consumption and of commerce as their fowl-houses or their farm-yards.

I shall, for brevity's sake, abstain from enlarging on this subject, merely observing that ample information can be obtained upon it by consulting the works of M.M. Coste and Fry, which are to be found in the libraries and bookshops in this city; and that in the streams in which it may be put into operation—if there are mill-dams upon them—the artificial construction to enable the fish to descend and ascend to and from the sea will still be requisite.

Having said so much on the decrease and restoration of salmon in Canada, let us now turn our attention for a few moments to their preservation in the rivers in which they still abound. These rivers I believe to be as valuable and inexhaustible as any others upon the face of the globe, but so circumstanced that their capabilities have not been developed, and that one year of neglect will cause their serious injury, if not their utter destruction, as salmon streams. Thev extend along the northern shore of the St. Lawrence from Quebec to Labrador, a distance of about 500 miles, and are many in number. They are chiefly held under lease from the Government of Canada, by the Hudson's Bay Company, who fish some of them in an unsystematic manner, with standing nets, because they can be conveniently and cheaply so fished, whilst others are left wholly to the destructive spear of the Indian. In the smaller streams on which the fishermen of the company are employed, a series of standing barrier-nets, (which kill indiscriminately every fish of every size and weight,) is used, a process, which in European rivers, would have long since banished salmon from them. But in Canada the high water in the spring enables some of the largest and strongest of the breeding fish to ascend the streams before those nets can be set, and when they get beyond them, they are comparatively safe in the mountain rivers and lakes which never hear a human footfall till winter-which congeals their surfaces into ice-tempts the poor Indian to tread their banks in pursuit of the bear, the marten, the mink and the otter.

In well regulated salmon fisheries in Europe, the fish—by the construction of proper weirs and reservoirs—are almost as much under the control of the managers as the sheep on their farms or the fowl in their poultry-yards. They can send such of them as they please to market, permit the fittest for the purpose to pass on to propagate their kind, allow the young to enjoy life till they become mature, and suffer the sick and unhealthy to return to their invigorating pastures in the depths of the ocean. But no portion of this system is practised in our American rivers. There is not a salmon weir in the province; and the consequence is, that young and old, kelt and grilse, worthless and unwholesome, the fish are killed by the undiscriminating net and the cruel spear.

It appears to me that the Hudson's Bay Company set little value on these fisheries, and maintain them merely as an accident appertaining to the fur trade which is far more profitable. The approaching termination of their lease and the consequent uncertainty of their tenure may perhaps appear a sufficient reason for their not incurring the expense of erecting weirs, by which much more profit could be made of their fisheries. Unproductive and wasteful as their mode of fishing is, the protection the Hudson's Bay Company affords is the only present safeguard for the existence of Salmon in Canada. I am persuaded that were that protection withdrawn for ONE SUM-MER, without the substitution of some other as effective, this noble fish would be utterly exterminated from our country. Fishermen from Gaspé, Rimouski, New Brunswick, Labrador, Newfoundland, the Magdalene Islands and the United States-whose numbers and skill would enable them to do thoroughly what the servants of the H. B. C. from their paucity and inexperience do ineffectuallywould swarm up our rivers, and with nets, spears, torches, and every other engine of piscine destruction, would kill, burn and mutilate every fish that ventured into the rivers. Already has this been attempted. For the last two or three years schooners from the United States, have regularly arrived, in the salmon season, at the Bay of Seven Islands, their crews well armed, and have set their nets in the river Moisie, in despite of the officers of the H. B. C. Similar circumstances have occurred at other fishing stations in the tributaries of the St. Lawrence; no means, that I am aware of, having been resorted to for punishing the aggressors or preventing a repetition of their outrages. The river Bersinies has this year (1856) been altogether in the hands of a speculating and rapacious American, who employed the spear of the Indian to furnish him with mutilated salmon, several boxes of which he brought to this city, in the month of September, when they were out of season, unfit for food and flavorless, having previously glutted the markets of Portland, Boston and New York with more palatable fish.

There can be but little doubt that many of the salmon streams in Lower Canada would be as productive, under proper management, as rivers in Europe for which large annual rents are paid; but it must
be admitted that the great distance at which they are situated from Civilization, the want of the means of intercourse between them and the inhabited parts of the country, the liability to trespass by armed ruffians, and the dreadful rigor of the climate in winter, present very serious obstacles to those who might wish to undertake such management : for obviating some of which I see no better method than the employment, during the summer months, of one or two armed steamers of light draught of water, such as are used for a similar purpose on the east coast of Denmark. These steamers should each have a commander on board, who should be a magistrate and empowered by parliament to act summarily in cases of infraction of the Fishery Laws, and beside supplying the lighthouses and other public works with stores, oil, building materials, etc., conveying the workmen managers and fishermen to their several stations, and protecting the lessees of the Province, might also be profitably employed as the means of transporting the fresh caught salmon from the several rivers, packed in ice, to the Rail-road Stations at St. Thomas and Quebec; from whence they could be distributed to the markets of Canada and the United States. Two Bills for the protection of salmon and trout in Lower Canada have recently become Acts of Parliament. These may possibly be productive of some good in civilized and inhabited districts, but must be utterly ineffective in those parts of the Province where there are no settled inhabitants, no magistrates, and no tribunals before which those who infringe the Law can be cited; and this is the case of all the best rivers in Lower Canada.

I cannot close these observations without endeavoring to impress on all who hear me, the necessity for prompt action in this matter; for there can be no doubt upon the mind of any man who is acquaintted with the localities, that if the King's Posts should be abandoned by the Hudson's Bay Company, before some well devised system be adopted for carrying on the work which they have hitherto effected, two melancholy results will be the inevitable consequences, viz.the salmon rivers will be taken possession of by hordes of lawless men, who will in no way contribute to the revenue of the country, but will quickly and recklessly exterminate the fish, and then desert our shores, leaving behind them no trace of their temporary occupation except the destruction they have wrought-and more terrible still-a whole tribe of Indians (the Montagnards) will be reduced to a state of positive starvation, for upon the Hudson's Bay Company they have hitherto been, and are now dependent for their ammunition, guns, and other means by which they obtain their food and clothing.

#### ON PRESERVING TIMBER FROM DECAY.

## ON PRESERVING TIMBER FROM DECAY.

### BY JOSEPH ROBINSON, TORONTO.

# Read before the Canadian Institute, December 20th, 1856.

The economic value of timber, and the immense outlay required for the constant restoration of works executed in the cheaper but least durable varieties of woods, have long directed the attention of practical men to the desirableness of discovering some process by which greater durability could be given to a material, in all other respects so admirably adapted to the objects in view, without affecting its original cost to such an extent as to render it no longer available for the numerous ordinary purposes to which it is now applied. To this subject, attention was anew directed in the last number of the *Canadian Journal*, in an article on the "Preservation of Timber ;"\* and it may not be out of place, by way of adding to the existing fund of information upon a subject of such general interest, to bring before the Institute, a well attested and valuable process invented and used by the eminent French chemist, Dr. Boucherie.

This process is the result of twenty years experimental labor and study, and is regarded in France and England as of the highest importance, being the only mode yet brought into practical and extensive application, by which the durability of woods, liable to decay, can be economically and effectually secured.

It accomplishes two objects : first, that of expelling the sap ; and, secondly, filling the pores of the timber with a preservative solution.

The mode of impregnating trees hitherto adopted, has been by saturation only, assisted sometimes by great pressure, and by previously subjecting the timber in cylinders to a vacuum or to heat.

Dr. Boucherie's process differs entirely: inasmuch as he applies a moderate pressure, and to one end only of the sap tubes of the tree, the effect of which is to expel the sap by the preserving liquor which takes its place. By some of the processes hitherto used, the sap (the fermentation of which is admitted to be the cause of decay) is allowed to remain in the tree; in the process now under review, the sap is expelled, and the tubes are thoroughly cleansed from the fermenting matter, which is displaced by an injected solution of a preservative nature.

The tubular structure of trees has been long known, but it has not

<sup>\*</sup> Vide Vol. I., p. 559. New Series.

been known that no connexion exists between the tubes laterally; and this is shewn by the interesting experiment of stopping up or shutting off certain of the sap-tubes at the end of the tree, leaving exposed such as form a word : which word, or name, by the injection of a coloring liquor, can be driven from one end of the tree to the other; so that wherever the tree is cut through, the name appears distinctly in colored letters on the exposed sections.

This experiment is interesting, not only in a scientific point of view; but it shews that none of the processes hitherto used, wherein lateral pressure is involved, can force any preserving liquor into a tree without a degree of violence, which must injure the fibre of the wood, and destroy its strength and use for many purposes.

The advantages which would result from expelling the sap and replacing it by an antisceptic fluid, have been long known; and the idea of effecting this by applying the fluid under pressure at the end of a piece of timber is not new, having been suggested and patented many years ago by Mr. Bethel. But the means then used did not accomplish the object in such a manner as to admit of its commercial application. Hence the more expensive process of creosoting has been adopted; where the timber is totally immersed in the oil, under pressure, a method which does not permit the sap to escape.

By the old process of violent pressure, the preserving liquor is forced at right angles to the tubes through the woody fibre of the tree, injuring its strength as well as its capability, in railway sleepers, for example, to resist the wear of the chairs; consuming at the same time an unnecessary amount of the preserving liquor, without (whatever pressure may be applied) thoroughly impregnating the timber, while one-sixth or one-eighth of the force only is necessary by the new process, and the portion alone requiring the preservative infusion, viz. the soft matter between the rings, is impregnated, the woody fibre remaining unbroken and undisturbed.

Another important advantage in Dr. Boucherie's process, is derived from the simplicity and moderate cost of the apparatus, which, for operations on a small scale, will not exceed £10 or £15, and for a railway of two hundred miles, under £50.

The practical application and entire success of this invention in Europe will be seen by the printed official reports. The first of these was made, by order of the French Government, in the year 1850, the second in 1852, and the third in 1856 : being an abstract from the official jury report of the Exposition Universelle of 1855, whereby it will be seen that the distinguished honor of one of the large gold medals was awarded to Dr. Boucherie, of which only four were conferred in all.

The mode of application is as follows :—Soon after the tree is felled, a saw-cut is made in the centre, through about nine-tenths of its section. The tree is slightly raised by a lever or wedge at its centre, and the saw-cut thereby partially opened; a piece of string is then placed round the cut, close to the outer circumference of the tree, the support is withdrawn, and the saw-cut closes on the string, thereby making a water-tight joint. An auger-hole is then bored obliquely into the saw-cut; a wooden tube is driven into the hole, the conical end of which is attached to a flexible pipe, which is in connexion with a cistern or reservoir, at an elevation of from 30 to 40 feet above the tree intended to be preserved.

When it is necessary to prepare timber in long lengths, a cap is placed at the end of the tree by screws or dogs. The most efficacious solution is composed of sulphate of copper and water, mixed in the proportion of 1 to 100. The strength is easily ascertained, by any intelligent workman, by an hydrometer;—and the cost of such a solution is so trifling, as to offer no impediment to its universal application for the purpose in view.\*

It would be difficult to enumerate all the classes to be benefitted by this invention, and the uses to which it may be applied. Railway companies, ship-builders, telegraph companies, and land owners, would alike benefit by it. Post and rail fencing, field gates, wood farm buildings, frame buildings, and dwellings in general, would last many additional years. Mr. R. Stephenson, the President of the Institute of Civil Engineers, in his inaugural address, adverts to the great consumption of railway sleepers by decay, and estimates it at 2,600,-000 per annum, costing upwards of £500,000. Taking the resistance

10

<sup>\*</sup> On comparing the above account of Boucherie's process with that described in the *Canadian Journal* (No. 6, pp. 559-561) and for which a patent was taken out in May, 1856, the two processes appear to be identical so far as the employment of hydraulic pressure is concerned, and if such is the case, this part of the patent is void.

The following is the text of the Patent Law bearing upon this point. "If at "the trial in any such action [for infringement of Patent,] it shall be made appa-"rent to the satisfaction of the Court...that the thing thus secured by Patent "was not originally discovered by the Patentee, or party claiming to be the "Inventor or Discoverer in the specification referred to in the Patent, but had "been in use, or had been described in some public work, anterior to the supposed "discovery of the Patentee.....the Patent shall be declared void." 13 and 14 Vict. "79, c. 8.—(Ed. Can. Jour.)

of the proposed sleepers to decay as the only basis of the calculation, a large proportion of this sum would be saved. Assuming the duration of the sleeper to be doubled, and taking into account the mechanical causes of destruction, a saving of  $\pounds 300,000$  per annum, would be effected to the railway interest in England alone.

From these data, the value of the invention in Europe will readily be seen, and although it has been patented in France and England, and, as it would seem, to some extent, in Canada, it is believed that the use in this Province is unfettered; 1st, because by the Statutes of Canada, no foreigner can obtain a patent monopoly in this country; and, 2nd, because, being already known and used in other countries, it cannot be patented here.

# THE CHINOOK INDIANS.

## BY PAUL KANE, TORONTO.

In accordance with an invitation of the Council of the Canadian Institute to communicate notices of some of the tribes of Indians amongst whom I have travelled, I selected the Chinooks, one of the tribes most remote from this part of the continent, and whose manners and customs are so much at variance with our own, as to render some notice of them, from personal observation, probably both novel and interesting. Other communications of the incidents and results of my travels among the Indians of the North West, having since appeared in the Journal, I have revised my account of the Chinooks, with a view to its appearance, along with the notices of the Walla Wallas, and others of the Aborigines of this continent in the New Series.

The Flat-Head Indians are met with along the banks of the Columbia river from its mouth eastward to the Cascades, a distance of about 130 miles; they extend up the Walamett river south about 30 or 40 miles, and through the district lying between the Walamett and Fort Astoria, now called Fort George. To the north they extend along the Cowlitz river and the tract of land lying between that and Puget's Sound. About two-thirds of Vancouver's Island is also occupied by them, and they are found along the coasts of Puget's Sound and the Straits of Juan de Fuca. The Flat-Heads are divided into numerous tribes, each having its own peculiar locality, and differing more or less from the others in language, customs, and manners.

Of these I have selected, as the subject of the present paper, the Chinooks, a tribe inhabiting the tract of country at the mouth of the Columbia river. Residing among the Flat-Heads, I remained from the fall of 1846 to the following autumn of 1847, and had consequently ample opportunity of becoming acquainted with the peculiar habits and customs of the tribe. They are governed by a Chief called Casenov. This name has no translation: the Indians on the west side of the Rocky Mountains differing from those on the east, in having hereditary names, to which no particuliar meaning appears to be attached, and the derivation of which is in many instances forgotten. Casenov is a man of advanced age, and resides principally at Fort Vancouver, about 90 miles from the mouth of the Columbia. I made a sketch of him while staying there, and obtained the following information as to his history :---Previous to 1829 Casenov was considered a great warrior, and could lead into the field 1,000 men, but in that year the Hudson's Bay Company and emigrants from the United States introduced the plough for the first time into Oregon, and the locality, hitherto considered one of the most healthy, was almost depopulated by the fever and ague.

Chinook Point, the principal settlement of the tribe, at the mouth of the river, where King Cumcomley ruled in 1811, was nearly reduced to one-half its numbers. The Klatsup village now contains but a small remnant of its former inhabitants. Wasiackum, Catlamet, Kullowith, the settlements at the mouth of the Cowlitz, Kallemo, Kattlepootle and Walkumup are entirely extinct as villages. On Sovey's Island there were formerly four villages but now there scarcely remains a lodge. They died of this disease in such numbers that their bodies lay unburied on the river's banks, and many were to be met with floating down the stream. The Hudson's Bay Company supplied them liberally with Quinine and other medicines, but the good effects of these were almost entirely counteracted by their mode of living and obstinacy in persisting in their own peculiar mode of treatment, which consisted principally in plunging into the river without reference to the particular crisis of the disease.

From these causes the numbers of the Indians have been very much reduced, and the effective power of the tribes so greatly diminished that the influence which Casenov owed to the number of his followers has correspondingly declined; his own immediate family consisting of ten wives, four children, and eighteen slaves, being reduced in one year to one wife, one child, and two slaves. Their decrease since that time has also been fearfully accelerated by the introduction of ardent spirits, which, in spite of prohibition and fines against selling it to Indians, they manage to obtain from their vicinity to Oregon city, where whiskey, or a poisonous compound called there *blue ruin*, is illicitly distilled. I have scarcely ever met with an Indian in that vicinity who would not get drunk if he could procure the means, and it is a matter of astonishment how very small a quantity suffices to intoxicate these unfortunate beings, although they always dilute it largely in order to prolong the pleasure they derive from drinking.

Casenov is a man of more than ordinary talent for an Indian, and he has maintained his great influence over his tribe chiefly by means of the superstitious dread in which they hold him. This influence was wielded with unflinching severity towards them, although he has ever proved himself the firm friend of the white man. For many years, in the early period of his life, he kept a hired assassin to remove any obnoxious individual against whom he entertained personal enmity. This brave, whose occupation was no secret, went by the name of Casenov's Sköcoom or evil genius. He finally fell in love with one of Casenov's wives who eloped with him. Casenov vowed vengeance, but the pair for a long time eluded his search, until one day he met her in a canoe near the mouth of the Cowlitz river and shot her on the spot. After this he lived in such continual dread of the lover's vengeance that for nearly a year he never ventured to sleep, but in the midst of a body guard of forty armed warriors, until at last he succeeded in tracing his foe out, and had him assassinated by the man who had succeeded him in his old office.

The Chinooks over whom Casenov presides carry the process of flattening the head to a greater extent than any other of the Flat-Head tribes. The process is as follows :-- The Indian mothers all carry their infants strapped to a piece of board covered with moss or loose fibres of cedar bark, and in order to flatten the head they place a pad on the forehead of the child, on the top of which is laid a piece of smooth bark bound on by a leathern band passing through holes in the board on either side and kept tightly pressed across the front of the head. A sort of pillow of grass or cedar fibres is placed under the back of the neck to support it.

This process commences with the birth of the infant, and is continued for a period of from eight to twelve months, by which time the head has lost its natural shape and acquired that of a wedge, the front of the skull becoming flat, broad, and higher at the crown, giving it a most unnatural appearance.

It might be presumed that from the extent to which this is

carried the operation must be attended with great suffering to the infant, but I never heard the infants crying or moaning, although I have seen their eyes seemingly starting out of the sockets from the great pressure. But on the contrary, when the bandages were removed I have noticed them cry until they were replaced.

From the apparent dullness of the children whilst under the pressure I should imagine that a state of torpor or insensibility is induced, and that a return to consciousness occasioned by its removal must be naturally followed by the sense of pain.

This unnatural operation does not however seem to injure the health, the mortality amongst the Flat-Head children not being perceptibly greater than amongst other Indian tribes. Nor does it seem to injure their intellect; on the contrary, the Flat-Heads are generally considered fully as intelligent as the surrounding tribes who allow their heads to preserve their natural shape; and it is from amongst the round-heads that the Flat-Heads take their slaves. They look with contempt even upon the whites for having round-heads, the *flat-head* being considered as the distinguishing mark of freedom. I may here remark, that, amongst the tribes who have slaves there is always something which conspicuously marks the difference between the slave and the free, such as the Chimseyan, who wear a ring in the nose, and the Babbenes who have a large piece of wood inserted through the under lip. The Chinooks, like all other Indian tribes, pluck out the beard on its first appearance.

I would give a specimen of the barbarous language of these people, were it not impossible to represent by any combination of the letters of our alphabet the horribly harsh, gasping, spluttering sounds which proceed from their throats, apparently unguided either by the tongue or lips. It is so difficult to acquire a mastery of their language that none have been able to attain it unless those who have been born amongst them. They have, however, by their intercourse with the English and French traders succeeded in amalgamating, after a fashion, some words of each of these tongues with their own, and have formed a sort of Patois, barbarous enough certainly, but still sufficient to enable them to communicate with the traders.

This Patois I succeeded, after some short time, in acquiring, and could converse with most of the chiefs with tolerable ease. Their common salutation is *Clah hoh ah yah*, originating, as I believe in their having heard in the early days of the fur trade a gentleman named Clark frequently addressed by his friends, "Clark, how are you?" This salutation is now applied to every white man, their own language affording no appropriate expression. Their language is also peculiar in containing no oaths, or any words expressive of gratitude or thanks.

Their habits are extremely filthy, their persons abounding with vermin, and one of their chief amusements consists in picking these disgusting insects from each others' heads and eating them. On my asking an Indian one day why he ate them, he replied that they bit him and he gratified his revenge by biting them in return. It may naturally be supposed that they are thus beset from want of combs or other means of displacing the intruders; but this is not the case, they pride themselves on carrying such companions about them, and giving their friends the opportunity of amusing themselves in hunting and eating them.

The costume of the men consists of a musk-rat skin robe, the size of one of our ordinary blankets, thrown over the shoulders, without any breech-cloth, moccassins or leggings. Painting the face is not much practised amongst them except on extraordinary occasions, such as the death of a relative, some solemn feast, or going on a war party. The female dress consists of a girdle of cedar bark round the waist. with a dense mass of strings of the same material hanging from it all around and reaching almost to the knees. This is their sole summer habiliment. They, however, in very severe weather add the muskrat blanket. They also make another description of blanket from the skin of the wild goose, which is here taken in great abundance. The skin is stripped from the bird with the feathers on, and cut into strips, which they twist so as to have the feathers outwards. This makes a feathered cord, and is then netted together so as to form a blanket, the feathers filling up the meshes, and rendering it a light and very warm covering. In the summer these are entirely thrown aside, not being in any case worn from feelings of delicacy, and the men go quite naked, though the women always wear the cedar petticoat.

The country which the Chinooks inhabit being almost destitute of furs they have little to trade in with the whites. This, coupled with their laziness—probably induced by the ease with which they procure fish, which is their chief subsistence—prevents their obtaining ornaments of European manufacture, consequently anything of the kind is seldom seen amongst them. They, however, wear long strings of small shells found on the coast called Ioquas, and used by them also as money.

A great traffic is carried on amongst all the tribes through the medium of these shells, which are found only at Cape Flattery, at the

#### THE CHINOOK INDIANS.

entrance to the Straits of De Fuca. They are fished up from the bottom of the sea, and are found an inch and a-half to two inches in length; they are white, slender, hollow, and tapering to a point, slightly curved, and about the size of the stem of an ordinary clay tobacco pipe. They are valuable in preportion to their length, and their value increases according to a fixed ratio, forty shells being the standard number required to extend a fathoms' length, which number is in that case equal in value to a beaver's skin, but if thirty-nine be found long enough to make the fathom it would be worth two beaver skins, if thirty-eight three skins, and so on, increasing one beaver skin for every shell less than the standard number.

The Chinooks evince very little taste in comparison with some of the tribes on the eastern side of the Rocky Mountains, in ornamenting either their persons or their warlike or domestic implements. The only utensils I saw at all creditable to their decorative skill were carved bowls and spoons of horn, and baskets made of roots and grass woven so closely as to serve all purposes of a pail in holding and carrying water. In these they even boil the salmon which constitute their principal food. This is done by immersing the fish in one of the baskets filled with water, into which they throw red hot stones until the fish is cooked, and I have seen fish dressed as expeditiously by them in this way as if done in a kettle over a fire by our own people.

The salmon is taken during the months of June and July in immense numbers in the Columbia river and its tributaries by spearing and with gill nets. They have also a small hand net something like our common landing net, which is used in rapids where the salmon are crowded together and near the surface. These nets are ingeniously contrived, so that when a fish is in them his own struggles loosen a little stick which keeps the mouth of the net open while empty, but which, when the net is full, immediately draws it together like a purse with the weight of the salmon and effectually secures the prey.

The salmon taken during this period of the year are split open and dried in the sun for their winter's supply. I have never seen salt made use of by any tribe of Indians for the purpose of preserving food, and they all evince the greatest dislike to salt meat.

I may here mention a curious fact respecting the salmon of the Columbia river; they have never been known to rise to a fly, although it has been frequently tried by gentlemen of the Hudson's Bay Company, with the very best tackle. The salmon go up the river as far as they possibly can and into all its tributary streams in myriads; it is, however, a well known fact that after spawning they never return to the sea, but all die in the river; the Columbia is hardly ever free from gill nets, and no salmon has ever been taken returning; and in the fall, wherever still water occurs, the whole place is tainted by their putrid bodies floating in immense masses. I have been obliged to travel through a whole night trying to find an encampment free from their disgusting effluvia.

The Chinooks also catch a considerable number of sturgeon, which here attain to an enormous size, weighing from four to six cwt.; this is done by means of a long-jointed spear handle seventy or eighty feet in length, fitted into, but not actually fastened to a barbed spearhead, to which is attached a line, with this they feel along the bottom of the river, where the sturgeon are found lying at the spawning season. Upon feeling the fish the barbed spear is driven in and the handle withdrawn. The fish is then gradually drawn in by the line, which being very long allows the sturgeon room to waste his great strength, so that he can with safety be taken into the canoe or towed ashore.

At the mouth of the river a very small fish, about the size of our Sardine, is caught in immense numbers. It is called there Uhlékun, and is much prized on account of its delicacy and extraordinary fatness. When dried this fish will burn from one end to the other with a clear steady light like a candle. The Uhlékuns are caught with astonishing rapidity by means of an instrument about seven feet long; the handle is about three feet, into which is fixed a curved wooden blade about four feet, somewhat the shape of a sabre, with the edge at the back. In this edge, at the distance of an inch and a-half, are inserted sharp bone teeth about an inch long. The Indian standing in the canoe draws this edgeways with both hands, holding it like a paddle, rapidly through the dense shoals of fish which are so thick that almost every tooth will strike a fish. One knock across the thwarts safely deposits them in the bottom of the canoe. This is done with such rapidity that the Indians will not use nets for this description of fishing.

There are few whales now caught on the coast, but the Indians are most enthusiastic in the chase. Upon a whale being seen blowing in the offing they rush down to their large canoes and push off, with ten or twelve men in each. The canoes are furnished with a number of strong seal skin bags filled with air, and made with great care and skill, capable of containing about ten gallons. To each bag is attached a barbed spear-head by a strong string about eight or nine feet long, and in the socket of the spear-head is fitted a handle five or Vol. II—B six feet in length. Upon coming up with the whale, the barbed heads, with the bags attached, are driven into it and the handles withdrawn. The attack is continually renewed until the whale is no longer able to sink from the buoyancy of the bags, when he is despatched and towed ashore. The blubber of the whale is much prized amongst them, and is cut into strips about two feet long and four inches wide, and eaten generally with their dried fish.

Clams and oysters are very abundant, and seals, wild ducks and geees, are taken in great plenty, but their fishing is so productive that the Indians subsist with little labour. They are also very fond of herrings' roe, which they collect in the following manner :—They sink ccdar branches to the bottom of the river, in shallow places, by placing upon them a few heavy stones, taking care not to cover the green foliage, as the fish prefer spawning on anything green, and they literally cover all the branches by next morning with spawn. The Indians wash this off in their water-proof baskets, to the bottom of which the roe sinks ; this is squeezed by the hands into little balls and then dried, and is very palatable.

The only vegetables in use amongst the Chinooks are the Camas and Wappattoo. The Camas is a bulbous root much resembling the onion in outward appearance but is more like the potato when cooked and is very good eating. The Wappattoo is somewhat similar but larger and not so dry or delicate in its flavour. They are found in immense quantities in the plains in the vicinity of Fort Vancouver, and in the spring of the year present a most curious and beautiful appearance, the whole surface presenting an uninterrupted sheet of bright ultramarine blue from the innumerable blossoms of these plants. They are cooked by digging a hole in the ground, then putting down a layer of hot stones, covering them with dry grass, on which the roots are placed ; they are then covered with a layer of grass, and on the top of this they place earth, with a small hole perforated through the earth and grass down to the vegetables. Into this they pour water, which, reaching the hot stones, forms sufficient steam to completely cook the roots in a short time, the hole being immediately stopped up after the introduction of the water. They often adopt the same ingenious process for cooking fish, meat, and game.

There is another article of food made use of amongst them, which from its disgusting nature I should have been tempted to omit, were it not a peculiarily characteristic trait of the Chinook Indian, both from its extraordinary character, and its use being confined solely to this tribe; it is, however, regarded only as a luxury and not as a general

article of food. The whites have given it the name of Chinook Olives, and it is prepared as follows :-- About a bushel of acorns are placed in a hole dug for the purpose close to the entrance of the lodge or hut, and covered over with a thin layer of grass, on top of which is laid about half a foot of earth; every member of the family for the next five or six months regards this hole as the special place of deposit for urine, which is on no occasion to be diverted from its legitimate receptacle. Even should a member of the family be sick and unable to reach it for this purpose, the fluid is carefully collected and carried thither. However disgusting such an cdoriferous preparation would be to people in civilized life the product is regarded by them as the greatest of all delicacies; so great indeed is the fondness they evince for this horrid preparation that even when brought amongst civilized society they still yearn after it and will go any distance to obtain it. A gentleman in charge of Fort George had taken to himself a wife, a woman of this tribe, who of course partook with himself of the best food the Fort could furnish; notwithstanding which, when he returned home one day his nostrils where regaled with a stench so nauseating that he at once enquired where she had deposited the Chinook olives, as he knew that nothing else could poison the atmosphere in such a manner. Fearful of losing her dearly-prized luxury she strenuously denied their possession : his nose however, led him to the place of deposit, and they were speedily consigned to the river. His mortification was afterwards not a little increased by learning that she had purchased the delicacy with one of his best blankets.

During the season the Chinooks are gathering Camas and fishing, they live in lodges constructed by means of a few poles covered with mats made of rushes, which can be easily moved from place to place; but in the villages they build permanent huts of split cedar boards. Having selected a dry place for the village, a hole is dug about three feet deep and about twenty feet square : round the sides of this, square cedar boards are sunk and fastened together with cords and twisted roots, rising about four feet above the outer level; two posts are sunk at the middle of each end with a crutch at top, on which the ridge pole rests, and boards are laid from thence to the top of the upright boards. Fastened in the same manner round the interior are erected sleeping places, one above another, something like the berths in a vessel, but larger. In the centre the fire is made, the smoke of which escapes by means of a hole left in the roof for that purpose. These lodges are filthy beyond description and swarm with vermin. The fire is procured by means of a flat piece of dry cedar, in which a small hollow is cut, with a channel for the ignited charcoal to run over; this piece the Indian sits on, to hold it steady, while he rapidly twirls a round stick of the same wood between the palms of his hands with the point pressed into the hollow of the flat piece. In a very short time sparks begin to fall through the channel upon finely frayed cedar bark placed underneath, which they soon ignite. There is a great deal of knack in doing this, but those who are used to it will light a fire in a very short time. The men usually carry these sticks about with them, as after they have been once used they produce the fire quicker.

The only warlike implements I have seen amongst the Chinooks were bows and arrows. The bows are made from the Yew tree, and the arrows are feathered and pointed with sharp bone. These they use with great precision.

Their canoes are hollowed out of the cedar, and some of them are very large, as this tree grows to an immense size in the neighbourhood. They make them exceedingly light, and from their formation they are capable of withstanding very heavy seas.

Slavery is carried on to a great extent along the North-West coast and in Vancouver's Island; and the Chinooks, considering how much they themselves have been reduced in numbers, still retain a large number of slaves. These are usually procured from the Chastay tribe who live near the Umqua, a river south of the Columbia emptying into the Pacific. They are sometimes seized by war parties, but are often bought from their own people. They do not flatten the head, nor is the child of one of them (although by a Chinook father,) allowed this distinguishing mark of freedom. Their slavery is of the most abject description : the Chinook men and women treat them with great severity, and exercise the power of life and death at pleasure. An instance of the manner in which the Chastay slaves are treated presented itself to my own observation one morning while I was out sketching on Vancouver's Island. I saw upon the rocks the dead body of a young woman whom I had seen a few days previously walking about in perfect health, thrown out to the vultures and crows. I mentioned it to a gentleman of the Hudson's Bay Company, who accompanied me to the lodge she belonged to, where we found an Indian woman, her mistress, who made light of her death, and who was no doubt the cause of it. She said a slave had no right to burial. She was furious on being told that the slave was as good as herself. "She, the daughter of a chief, no better than a slave !" She then stalked out of the lodge with great dignity; the next morning she had taken

down the lodge and was gone. I was also told by an eye witness, of a chief who, having erected a colossal idol of wood, sacrificed five slaves to it, barbarously murdering them at its base, and asking in a boasting tone who among them could afford to kill so many slaves. One of these slaves was a handsome girl who had lived from her infancy in his family, and begging most piteously for life, reminded him of the care she had taken of his children and all the services she had rendered; but her pleadings were of no avail, and the brutal wretch with his own hand plunged a knife four times into her body before she ceased her appeals for mercy. The only distinction made in her favour was that she was buried, instead of being, like her miserable companions, thrown out on the beach.

The principal amusement of the Chinooks is gambling, which is carried to great excess amongst them. You never visit the camp but you hear the monotonous gambling song of "he ha, ha," accompanied by the beating of small sticks on some hollow substance. Their games do not exceed two or three, and are of a simple nature. The one most generally played consists in holding in each hand a small piece of stick the thickness of a goose quill and about an inch and a-half in length, one plain and the other distinguished by a little thread wound round it, the opposite party being required to guess in which hand the marked stick is to be found. A Chinook will play at this simple game for days and nights together, until he has gambled away everything he possesses, even his wife. They play, however, with much equanimity, and I never saw any ill-feeling evinced by the loser against his successful opponent. They will cheat if they can, and pride themselves on its success ; if detected no unpleasant consequence follows, the offending party being merely laughed at and allowed to amend his play.

Another game to which the Chinooks are very partial is played by two or three on each side. The rivals sit on the ground opposite each other with the stakes lying in the centre, one begins with his hands on the ground in which he holds four small sticks covered from sight by a mat, these he arranges in any one of a certain number of forms prescribed by the rules of the game, and his opponent on the opposite side endeavours to guess which form he has chosen; if successful a mark is stuck up in his favour, and the sticks are handed to the next, if not the player counts and still goes on till discovered. When those on one side have gone through, the others commence. At the conclusion the marks are counted and the holder of the greater number wins. This game is also accompanied by singing, in which all the bystanders join.

Another game which I have seen amongst them is called Al-kolloch, and is one that is universal along the Columbia river. It is considered the most interesting and important as it requires great skill. A smooth level piece of ground is chosen, and a slight barrier of a couple of sticks laid lengthways is made at each end. These are forty or fifty feet apart and a few inches high. The two opponents, stripped naked, are armed each with a very slight spear about three feet long and finely pointed with bone. One of them takes a ring made of bone or some heavy wood, about three inches in diameter, and wound round with cord, on the inner circumference of which are fastened six beads of different colours at equal distances, to each of which a separate numerical value is attached; the ring is then rolled along the ground to one of the barriers and is followed at the distance of two or three yards by the players, and as the ring strikes the barrier and is falling on its side the spears are thrown so that the ring may fall on them; if only one of the spears should be covered by the ring the owner of it counts according to the coloured bead over it. But it generally happens, from the dexterity of the players, that the ring covers both spears, and each count according to the colours of the beads above his weapon. They then play towards the other barrier, and so on until one party has attained the number agreed upon for game.

The Chinooks have tolerably good horses, and are fond of racing, at which they bet considerably; they are expert jockeys and ride fearlessly. They also take great delight in a game with a ball, which is played by them in the same manner as by the Cree, Chippewa, and Sioux Indians. Two poles are erected about a mile apart, and the company is divided into two bands armed with sticks, having a small ring or hoop at the end, with which the ball is picked up and thrown to a great distance, each party then strives to get the ball past their own goal. There are sometimes hundreds on a side, and the play is kept up with great noise and excitement. At this game they also bet heavily, as it is generally played between tribes or villages.

The sepulchral rites of this singular tribe of Indians are too curious to be entirely omitted. Upon the death of a Chinook the body is securely tied up in rush matting and placed in the best canoe they can procure, without any peculiar ceremonies. This canoe is as highly decorated as the family of the deceased can afford. Tin cups, kettles, plates, pieces of cotton, red cloth, and furs, and in fact everything which they themselves most value, and which are most difficult for them to obtain, are hung round the canoe ; inside, beside the body

they place paddles, spears, bows and arrows, and food, with everything else which they consider necessary for a very long journey. I have even found beads, Ioquas shells, brass buttons, and small coins in the mouths of the skeletons. The canoe is then taken to the bur ial place of the tribe, generally selected for its isolated situation. The two principal places are rocky islands in the lower part of the Columbia River. One is called Coffin Rock from the appearance it presents, covered with the raised biers of the deceased members of the tribe. To these they tow the canoe, which is then either fastened up in a tree or supported on a sort of frame four or five feet from the ground made of strong cedar boards, and holes bored in the bottom of the canoe to let the water run out; it is then covered with a large piece of bark to protect it from the rain. Before leaving, the usefulness of every article left with the corpse is destroyed, by making holes in the kettles, cans, and baskets, cracking the bows, arrows, and spears, and if there is a gun they take the lock off, believing that the Great Spirit will mend them upon the deceased arriving at the hunting grounds of their Elysium. The greatest crime which an Indian can commit in the eyes of his people is that of desecrating one of these canoes, and it very seldom happens that the slightest thing is removed.

In obtaining a specimen of one of the peculiarly formed skulls of the tribe I had to use the greatest precaution, and ran no small risk not only in getting it, but in having it in my possession afterwards. Even the voyageurs would have refused to travel with me had they known that I had it among my collections, not only on account of the superstitous Iread in which they hold these burial places, but also on account of the danger arising from a discovery, which might have cost the lives of the whole party.

A few years before my arrival at Fort Vancouver, Mr. Douglass, who was then in charge, heard from his office in the Fort the report of a gun inside the gates ; this being a breach of discipline he hurried out to enquire the cause of so unusual a circumstance, and found one of Casenov's slaves standing over the body of an Indian whom he had just killed, and in the act of reloading his gun with apparent indifference, Casenov himself standing by. On Mr. Douglass arriving at the spot, he was told by Casenov, with an apology, that the man deserved death according to the laws of the tribc, who, as well as the white man inflicted punishment proportionate to the nature of the offence. In this case the crime was one of the greatest an Indian could be guilty of, namely, the robbing the sepulchre canoes. Mr. Douglass after severely reprimanding him allowed him to depart with the dead body.

Sacred as the Indians hold their burial places, Casenov himself, a short time after the latter occurrence, had his only son buried in the cemetery of the fort. He died of consumption-a disease very frequent amongst all Indians-proceeding no doubt from their constant exposure to the sudden vicissitudes of the climate. The coffin was made sufficiently large to contain all the necessaries supposed to be required for his comfort and convenience in the world of spirits. The chaplain of the fort read the usual service at the grave, and after the conclusion of the ceremony, Casenov returned to his lodge, and the same evening attempted, as narrated below, the life of the bereaved mother, who was the daughter of the great chief generally known as King Comcomly, so beautifully alluded to in Washington Irving's "Astoria." She was formerly the wife of a Mr. McDougall, who bought her from her father for, as it was supposed, the enormous price of ten articles of each description, guns, blankets, knives, hatchets, &c., then in Fort Astoria. Comcomly, however, acted with unexpected liberality on the occasion by carpeting her path from the canoe to the Fort with sea otter skins, at that time numerous and valuable, but now scarce, and presenting them as a dowry, in reality far exceeding in value the articles at which she had been estimated. On Mr. McDougall's leaving the Indian country she became the wife of Casenov.

It is the prevailing opinion of the chiefs that they and their sons are too important to die in a natural way, and whenever the event takes place they attribute it to the malevolent influence of some other person, whom they fix upon, often in the most unaccountable manner, frequently selecting those the most dear to themselves and the deceased. The person so selected is sacrificed without hesitation. On this occasion Casenov selected the afflicted mother, notwithstanding she had during the sickness of her son been most assiduous and devoted in her attentions to him, and of Casenov's several wives she was the one he most loved ; but it is the general belief of the Indians on the west side of the mountains, that the severer the privation they inflict upon themselves the greater is therefore the manifestation of their grief, and the more pleasing to the departed spirit. Casenov assigned to me, as an additional motive for his wish to kill his wife, that as he knew she had been so useful to her son and so necessary to his happiness and comfort in this world, he wished to send her with him as his companion on his long journey. She, however, escaped into the woods, and next morning reached the Fort, imploring protection; she was accordingly secreted for several days until her own relations took her home to Chinook Point. In the meantime a woman was found murdered in the woods and the act was universally attributed to Casenov or one of his emissaries.

I may here mention a painful occurence which took place on Thompson's River, in New Caledonia, in further illustration of this peculiar superstition. A Chief dying, his widow considered a sacrifice as indispensable, but having selected a victim of rather too much importance, she was unable for some time to accomplish her object ; at length the nephew of the chief, no longer able to bear the continual taunts of cowardice which she unceasingly heaped upon him, seized his gun and started for the Company's Fort on the river, about twenty miles distant. On arriving, he was courteously received by Mr. Black, the gentleman in charge of the Fort, who expressed great regret at the death of his old friend the chief. After presenting the Indian with something to eat, and giving him some tobacco, Mr. Black turned to leave the room, and while opening the door was shot from behind by his treacherous guest and immediately expired. The murderer succeeded in escaping from the Fort, but the tribe, who were warmly attached to Mr. Black, took his revenge upon themselves and hunted him down. This was done more to evince their high esteem for Mr. Black than from any sense of impropriety in the customary sacrifice.

I never heard any traditions amongst the Chinooks as to their former origin, although such traditions are common among the Indian tribes on the east side of the Rocky mountains. They do not believe in any future state of punishment, although in this world they suppose themselves exposed to the malicious designs of the Sköcoom or evil genius, to whom they attribute all their misfortunes and ill luck. The good spirit is called the *Hias Soch-a-li Ti-yah*, that is the Great High Chief from whom they obtain all that is good in this life, and to whose happy and peaceful hunting grounds they believe they shall all eventually go, to reside for ever in comfort and abundance.

The medicine men of the tribe are supposed to possess a mysterious influence with these two spirits, either for good or evil, and of course possess great power in the tribe. These medicine men form a secret society, the initiation into which is accompanied with great ceremony and much expense. I witnessed, whilst amongst them, the initiation of a canditate, which was as follows :-- The canditate has to

prepare a feast for his friends and all who choose to partake of it, and make presents to the other medicine men. A lodge is prepared for him, which he enters, and remains alone for three days and nights. without food, whilst those already initiated keep dancing and singing round the lodge during the whole time. After this fast which is supposed to endue him with wonderful skill, he is taken up apparently lifeless and plunged into the nearest cold water, where they rub and wash him until he revives. This they call "washing the dead." As soon as he revives he runs into the woods, and soon returns dressed as a medicine man, in a costume which generally consists of the light down of the goose stuck all over the body and head with thick . grease, and a mantle of friezed cedar bark. With the medicine rattle in his hand he now collects all his property, blankets, shells and ornaments, and distributes the whole amongst his friends, trusting for. his future support to the fees of his profession. The dancing and singing are still continued with great vigour during the division of the property, at the conclusion of which the whole party again sit down to feast, apparently with miraculous appetites, the quantity of food consumed being perfectly incredible.

I witnessed one day their mode of treatment of the sick whilst passing through a village. Hearing a horrible noise in one of the lodges, I entered it, and found an old woman supporting one of the handsomest girls of the tribe I had ever seen; cross-legged and naked in the middle of the room sat the medicine man with a wooden dish full of water before him, and twelve or fifteen other men sitting round the lodge. The object in view was to cure the girl of a disease affecting her side. As soon as my presence was noticed a space was cleared for me to sit down. The officiating medicine man appeared in a state of profuse pespiration from the exertions he had used, and soon took his seat amongst the rest as if quite exhausted ; a younger medicine man then took his place in front of the bowl and close beside the patient; throwing off his blanket he commenced singing and gesticulating in the most violent manner, whilst the others kept time by beating with little sticks on hollow wooden bowls and drums, singing continually. After exercising himself in this manner for about half an hour, until the pespiration ran in streams down his body, he darted suddenly upon the young woman catching hold of her side with his teeth and shaking her for a few minutes, as one dog does another in fighting. The patient seeming to suffer great agony. He then relinquished his hold, and cried out he had got it, at the same time holding his hands to his mouth, after which he plunged

them in the water, and pretended to hold down with great difficulty the disease which he had extracted lest it might spring out and return to its victim. At length having obtained the mastery over it, turning himself round to me in an exulting manner, he held something up between the finger and thumb of each hand, which had the appearance of a piece of cartlage, whereupon one of the Indians sharpened his knife and divided it in two, leaving one end in each hand. One of the pieces he threw into the water and the other into the fire, accompanying the action with a diabolical noise which none but a medicine man can make ; after which he got up perfectly well satisfied with himself, although the poor patient scemed to me anything but relieved by the violent treatment she had undergone.

My principal object in travelling among the Indian tribes of the Far West was to obtain accurate sketches of their Chiefs, medicine men, &c., and representations of their most characteristic manners and customs, but it was only by great persuasion that I could induce the Indians to allow me to take their portraits. They had an undefined superstitious dread of losing something by the process, as though in taking their likeness something pertaining to themselves was carried off. The women, moreover, had the idea that the possessor of their picture would hold an unlimited influence over them. In one case I had taken the likeness of a woman at the Cowlitz river, and on my return about three months afterwards, I called at the lodge of Kisscox, the chief of the tribe, where I had been in the habit of visiting frequently, and had always been received with great kindness, but on this occasion I found him and his family unusually distant in their manner, and the children even running away from me and hiding; at last he asked me if I had not taken the likeness of a woman when last amongst them, I said I had, and mentioned her name, "Cawitchum," a dead silence ensued, nor could I get the slightest answer to my enquiries. Upon leaving the lodge I met a half-breed, who told me that Cawitchum was dead, and that I was supposed to be the cause of her death. The silence was occasioned by my having mentioned a dead person's name, which is considered disrespectful to the deceased, and unlucky. I immediatly left the neighbourhood, well knowing the danger that would result from my meeting with any of her relations.

Upon trying to persuade another Indian to sit for his likeness he asked me repeatedly if it would not endanger his life. Being very much in want of tobacco he at length appeared convinced hy my assurances that it could do him no harm, but when the picture was finished he held up the tobacco and said it was a small piece to risk his life for. I asked another Indian while he was sitting in his lodge surrounded by his eight wives, for the same favor, but the ladies all commenced violently jabbering at me until I was glad to get off: he apparently was much gratified at the interest which his wives took in his welfare. I however met him alone some short time afterwards and got him to consent, with my usual bribe, a piece of tobacco. I could relate numerous instances of this superstitious dread of portrait painting, but the foregoing sufficiently illustrates the general feeling on the subject.

I shall conclude this paper by relating a legend told me by an old Indian while paddling in a canoe past an isolated rock on the shores of the Pacific, as it gives an idea of the general character of the legends on the coast, which are however very few, and generally told in an unconnected and confused manner. The rock with which the following Indian legend is associated. rises to a height of between six and seven feet above the water, and measures little more than four feet in circumference. I could not observe any very special peculiarity in the formation of this rock while paddling past it in a canoe; and, at least from the points of observation presented to my eye, no resemblance to the human figure-such as the conclusion of the legend might lead us to anticipate,-appeared to be traceable. Standing, however, as this rock does, entirely isolated, and without any other visible for miles around, it has naturally become an object of special note to the Indians, and is not uncalculated, from its solitary position, to be made the scene of some of the fanciful creations of their superstitous credulity.

"It is many moons since a Nasquawley family lived near this spot. It consisted of a widow with four sons; one of them was by her first husband, the other three by her second. The three younger sons treated their elder brother with great unkindness, refusing him any share of the produce of their hunting and fishing; he, on the contrary, wishing to conciliate them, always gave them a share of his spoils. He in fact was a great medicine man, although this was unknown to them, and being tired of their harsh treatment, which no kindness on his part seemed to soften, he at length resolved to retaliate. He accordingly one day entered the lodge where they were feasting and told them that there was a large seal a short distance off. They instantly seized their spears and started in the direction he pointed out, and coming up to the animal the eldest drove his spear into it. This seal was 'a great medicine,' a familiar of the

elder brother who had himself created it for the occasion. The foremost of them had no sooner driven in his spear than he found it impossible to disengage his hand from the handle or to draw it out; the two others drove in their spears and with the like effect. The, seal now took to the water, dragging them after it, and swam far out to sea. Having travelled on for many miles they saw an island in the distance, towards which the seal made ; on nearing the shore they found that they could, for the first time, remove their hands from their spears; they accordingly landed, and supposing themselves in some enemies' country, they hid themselves in a clump of bushes from observation. While lying concealed they saw a diminutive canoe coming round a point in the distance, paddled by a very little man, who, when he came opposite to where they were, anchored his boat with a stone attached to a long line, without perceiving them. He now sprang over the side, and diving down, remained a long time under water, at length he rose to the surface and brought with him a large fish, which he threw into the boat; this he repeated sever-al times, each time looking in to count the fish he had caught. The three brothers being very hungry, one of them offered to swim out while the little man was under water and steal one of the fish; this he safely accomplished before the return of the fisherman, but the little fellow no sooner returned with another fish than he discovered that one of those already caught was missing, and stretching out his hand he passed it slowly along the horizon, until it pointed directly to their place of concealment. He now drew up his anchor and paddled to the shore, and immediately discovered the three brothers ; and being as miraculously strong as he was diminutive, he tied their hands and feet together and throwing them into his cance, jumped in and paddled back in the direction from whence he had come. Having rounded the distant point where they first descried him, they came to a village inhabited by a race of people as small as their captor, their houses, boats, and utensils being all in proportion to themselves. The three brothers were taken out and thrown bound as they were into a lodge, while a council was convened to decide upon their fate. During the sitting of the council an immense flock of birds resembling geese, but much larger, pounced down upon the inhabitants and commenced a violent attack. These birds had the power of throwing their sharp quills like the porcupine, and though the little warriors fought with great valour they soon became covered with the piercing darts, and all sunk insensible on the ground : when all resistance had ceased the birds took to flight and disap-

peared. The three brothers had witnessed the conflict from their place of confinement, and with much labour had succeeded in releasing themselves from their bonds, when they went to the battle ground and commenced pulling the quills from the apparently lifeless bodies, but no sooner had they done this than all instantly returned to consciousness. When all of them had become well again they wished to express their gratitude to their preservers and they offered to grant whatsoever they should desire. The three brothers therefore requested to be sent back to their own country. A council was accordingly called to decide upon the easiest mode of doing so, and they eventually determined upon employing a whale for the purpose. The three brothers were then seated upon the back of the monster and proceeded in the direction of Nasquawley : however, when they had reached about half way the whale began to think what a fool he was for carrying them instead of turning them into porpoises and letting them swim home themselves. Now the whale being a "Soch-a-li-Tivah" or great spirit-that is the highest of all animal spirits-but of course inferior to the "Hias Soch-a-li Tiyah," who is the Great Spirit over all things, was able to do this at will, and he accordingly turned the three brothers into porpoises. This therefore is the way that the porpoises first came into existence, and accounts for their being constantly at war with the seals, one of which species was the cause of their first misfortunes. After the three brothers had so strangely disappeared their mother came down to the beach and remained there for days watching for their return and bewailing their absence with tears. While thus engaged one day the whale happened to pass by and taking pity on her distress he turned her into that stone."

### NOTE ON THE OXALATE OF MANGANESE.

BY HENRY CROFT, D.O.L., F.C.S., PROFESSOR OF CHEMISTRY, UNIVERSITY COLLEGE, TORONTO.

Read before the Canadian Institute, December 20th, 1856.

In Gmelin's Handbuch, Vol. IV., the oxalate of the protoxide of manganese is described as having been obtained by Graham, combined with 5 equivalents (24, 16 per cent.) of water, by precipitation of a solution of one part of manganese-salt in 100 of water, by means of oxalate of potassa; and this compound is stated to lose no water at 212°.F. Nothing is said with regard to the amount of water in the precipitate obtained from concentrated manganese solutions by oxalic acid.

There is evidently some error in the above statement, for the formula MnO,  $C^2O^3+5$  HO requires 38,60 per cent. of water, and Mn O,  $C^2O^3+3$  HO requires 27.39.

In the 89th volume of the Annalen der Chemie and Pharmacie, Hausmann and Löwenthal give an analysis of the oxalate obtained by acting on freshly precipitated carbonate of manganese with oxalic acid, from which they deduce the formula Mn O,  $C^2O^3+2$  HO, for the salt dried at 212°. F.

The following experiments were made for the purpose of explaining the discrepancy.

Strong solutions of sulphate of manganese were precipitated by saturated solutions of oxalic acid, a granular white precipitate was obtained in both cases, which did not lose water at 212°. F. I. and II.

Similar solutions were mixed when boiling. III.

Sulphate of manganese was dissolved in 30 parts of water, and oxalic acid added, a light pinkish crystalline precipitate was formed after a time, which, in the course of a few days, changed into a perfectly white granular powder. IV.

Sulphate of manganese was dissolved in 30 parts of water, and a solution of oxalate of potassa added, a light pinkish crystalline precipitate gradually formed, having the appearance and lightness of benzoic acid, it absorbed and retained water like a sponge, and remained unchanged in the air at ordinary temperatures, but became perfectly white at 212°. F. V.

Sulphate of manganese was dissolved in 100 parts of water, and oxalate of potassa added; the same pink salt was obtained. VI. This should be the compound described by Graham, with 5 HO.

#### WHITE SALT.

| VI.       | 1.4395 | 26    | 66   | 0.567 | 66            | æ      | 36.64 | 66        | **  |
|           | 1.5300 | 66    | \$\$ | 0.597 | 66            | ,<br># | 36,39 | 66        | 66  |
|           |        |       |      |       |               |        |       |           |     |
|           |        |       |      |       | 34            |        | 00.00 |           |     |

Mean 36.62.

1.5300 heated to  $212^{\circ}$ .F. lost 0.134 HO = 8.75 per cent. HO, and became perfectly white.

The formula MnO,  $C^*O^3+3$  HO requires 36.09 per cent. MnO and one equivalent of water would = 9.09 per cent.

The red oxide of manganese is obtained by heating this salt, in a crystalline form; the complete conversion of the protoxide into the red oxide is only effected after a rather long roasting.

Burin du Buisson is of opinion that pure salts of the protoxide of manganese are colourless when in an anhydrous state, but reddish when hydrated, while Reithner and others ascribe the red colour to the presence of a salt of the sesquioxide. The pink colour of the above hydrate can scarcely be owing to the latter cause, inasmuch as the salt is produced both by oxalic acid and by oxalate of potash; and the salt with 2 HO is generally obtained perfectly white. (This salt is described by Liebig as having a tinge of pink, but in my experiments it was always white.) The pink crystallized salt changes in a warm atmosphere, even when kept in a close vessel, into the white compound, evolving water.

The oxalate dissolves readily in a hot solution of oxalate of ammonia, and crystalline compounds can be obtained as already described by Winkelblech: these crystalline crusts, however, seem to vary much in their composition, and are probably combinations of the true double salt with variable proportions of oxalate of ammonia, similar to the magnesia compounds lately described by Souchay and Leussen.

### REVIEWS.

Canada at the Universal Exhibition of 1855.—Printed by order of the Legislative Assembly. Toronto: John Lovell, 1856.

The success which attended the Canadian exhibition at London, in 1851, naturally led to the expectation that no efforts would be spared to present at Paris, in 1855, a correct representation of the Natural Productions and Industry of this vast Province.

 $\mathbf{32}$ 

It was a triumph of no common order to receive a public acknowledgement of "the superiority of the Canadian collection at London, as far as the mineral kingdom was concerned, to all countries that forwarded their products to the Exhibition," and the "very remarkable specimens of the chief varieties of Canadian timber," together "with the fine supply of wheats, every sample of more than average excellence." so favorably noticed by the jurors, inspired the hope that Canada would be fairly represented and appreciated at the great Paris Exhibition, in 1855. Nor has this hope been disappointed, when the vast distance which separated us from the scene of rivalry and display is considered, and the facilities which wealth, leisure, and position, conferred on the majority of European Exhibitors.

With few exceptions, it could scarcely be a subject of personal pecuniary interest to the farmers and manufacturers of this country to send the results of their industry or skill to compete with ages of experience in Europe. Even the products of our forests, though if known in all their variety and excellence beyond our borders, they would doubtless create a profitable market. yet, if their representation had been altogether left to the unremunerated zeal of private contributors, it is scarcely probable that even they would have been fairly represented. Hence the Provincial Committee, appointed to secure a fitting representation of the products of this Country at the Paris Exhibition, arrived at the conclusion, that any attempt to induce voluntary efforts by local fairs, such as those which were held at Toronto and Montreal previous to the Exhibition of 1851, would be fruitless, and that it would be absolutely necessary that the Provincial Committee should have the authority to purchase such articles as they deemed it expedient to transmit to Paris.

In accordance with this suggestion the Canadian Government appropriated a sufficient sum to cover all the expenses of the transit and ultimate purchase of the articles sent. It was further suggested by the Executive Committee that every effort should be made to secure a satisfactory representation of the great staple products of Canada-Minerals, Agricultural Products, and Timber-so successfully represented at London in 1851; and also, that the manufacturcs of the country should be exhibited in their progressive stages up to the highest point of perfection. Local exhibitions were held at Toronto and Montreal, and selections made as in 1851, for transmission to Paris. Hence it appears that no effort was spared to have Canada properly represented, and with what success we are informed by Mr. Taché's Report of "Canada at the Universal Exhibition of 1855."

VOL. II.---C

# 34 REVIEWS-CANADA AT THE UNIVERSAL EXHIBITION.

We are told that the display of the products of Mines, Forests, and Agriculture "was truly magnificent," and that the premiums obtained were such as to give full satisfaction to all who were interested in exhibiting the natural resources of Canada to the greatest advantage. The samples of agricultural product were very fine, and included every variety of the cereals cultivated in this country. Fifty-six different kinds of minerals are enumerated in the catalogue of articles sent, and sixty-four kinds of woods, together with numerous models in wax of the vegetables and fruits grown in the Province. The Executive Council close their report, which forms the first part of Mr. Taché's volume, "with the consoling reflection that the most complete success has crowned the undertaking, for the due carrying out of which, the country has manifested such earnest solicitude."

The two special Commissioners, Sir W. Logan and Mr. Taché, divided the duties of their office, the former undertaking the arrangement of the exhibition; the latter, the diffusion of information respecting Canada throughout Europe, and of the entire exhibition throughout Canada. These efforts resulted in attracting a larger share of public attention to Canada, in proportion to its population, than to any other country; and, Count Jaubert, in his work entitled "La Botanique à l'exposition universelle de 1855," reproachfully says, "now we can form an estimate of the value of those few arpents of snow ceded to England with such culpable carelessness by the Government of Louis XV."

The testimony of many distinguished men may be adduced to shew that the most complete success crowned the efforts made by this country at the Universal Exhibition, and in one history of that wonderful pageant, Mr. Robin, the author, remarks : "the efforts made by Canada, that old French Colony, to make a suitable appearance at the great Exhibition of 1855, efforts which have resulted, moreover, in the most complete success, coupled with the undoubted importance of that fine country, whose future cannot be otherwise than brilliant, render it a duty on our part to devote to it a distinct chapter." Canada obtained one grand medal of honour (Sir W. Logan,) and is the only colony which secured that distinction-one medal of honour for the collection of woods and grains, thirteen silver medals, thirty bronze medals, and forty-eight 'honorable mentions,'-making altogether ninety-three prizes carried off at Paris, while at London the number of prizes awarded to this country amounted only to sixty-three. Mr. Romain's Steam Cultivator was not exhibited, it having been purchased and withdrawn from the exhibition by the celebrated Agricultural Machine makers, Crosskill & Co., and is now designated as "Romain's Canadian Steam Cultivator."

Mr. Taché published in Paris his prize essay entitled "Esquisse sur la Canada consideré sous le point de vue économiste,"-- and in the report before us a translation of this little work is given. He also published a descriptive catalogue of the productions of Canada, exhibited in Paris in 1855, and at the end of each enumeration of articles embraced in the different classes, he gives their prices in this country, and appends remarks as to their distribution, commercial importance, &c. With reference to our progress in mining industry, we find that the exportations of metals from our mines was valued at £8,350 in 1852, and £74,000 in 1854. Attention is directed to the value of the Tamarack, as a serviceable wood, rapidly growing into favour in Europe. The oil of the black porpoise, Delphinus minor, is particularly noticed, on account of its remarkable property of retaining its fluidity at a very low temperature. Porpoise leather is altogether an article of Canadian manufacture, and possesses many valuable peculiarities. Birds'-eye maple was found to be excluded from general use in the Paris cabinet manufactories, on account of its price, and Mr. Taché very appropriately mentions the fact that it is used for fuel in Canada, and ought to be supplied at a price little above that of the commonest woods.

We are next furnished with "Observations on the Exhibition," which have already been published in the form of correspondence, addressed, during the exhibition, to a portion of the French Press of Lower Canada; these are republished in the Report, by order of the House of Assembly. Among many facts of interest to Canadians, contained in these instructive and attractive letters, we are told that the total area of the Crystal Palace at London, in 1851, was about 800,000 square feet—that of the Palace of Industry and its Annexe at Paris, exclusive of the Palace used for the exhibition of Fine Arts, 1,200,000 feet. The number of exhibitors at London was 14,840, at Paris 20,839.

Bearing in mind the depopulated condition of many of our Canadian rivers, which once swarmed with fish, Mr. Taché notices the illustrations of the new art of Pisciculture, and the specimens of young fry and spawn exhibited by Mr. Mallet, "who rears pike, carp, eels, &c., as other people do puppies." Various plans of fish-ways up mill dams are eminently suggestive, and ought to be introduced on every Canadian river where a dam is constructed, tending to oppose the upward progress of the fish in spawning time, and thus to depopulate our rivers. Mr. Letailleur's success in replacing rare furs by sheep skins prepared and dyed in various ways and colours, appears likely to commend itself to Canadian manufacturers.

Comparing the Canadian part of the Exhibition with its European rivals, Mr. Taché says :

"In the first class, embracing all that relates to the extraction of mineral substances, and to the minerals themselves, we were among the last, and far behind most countries, in regard to metallurgical operations, for the very simple reason that we are deficient in the population and capital which carry on, and still more deficient in the men of science, who in France, England, Austria, Prussia, Belgium, and other countries, direct and enlighten the labors of the mine. But if we proceed to an examination of the minerals in their natural state, our section at once assumed the first rank, and no country was in a condition to compete with us for a moment, either in the aggregate or the details of the department. The class of Canadian minerals was the most complete, and had the advantage of displaying at a glance to the learned observer the geological configuration of the country, with reference to the industrial results which it may yield. For this success, which is a mere repetition of that obtained at London in 1851, Canada is indebted entirely to the geological commissioners; and this shews to demonstration, the necessity of continuing the labors of that commission on a more liberal scale. We possess in the bosom of the earth the untouched riches, which in England have been the main element of industrial and commercial greatness; but the conditions of progress towards that greatness, are the light of science, and extensive enterprise. Mining operations cannot be profitably conducted on a small scale.

When we reflect that the iron which abounds in Canada is nearly of the same quality as that of Sweden, that it is found in places, surrounded by immense forests, and that, we have at hand the stone, saud, and other matters which are necessary for the smelting, moulding, and casting of the metal, we may well wonder that every year we import from England, Sweden, and the United States, manufactured iron to the amount of more than  $\pounds 1,000,000$ . But, we must again observe, success attends such enterprises, only when undertaken on a grand scale, whatever the abundance of the raw material. The working of an iron mine is not for limited means, nor to be carried on on a petty scale. A cheap market must be a full market. In Europe blast furnaces are now built, capable of smelting 80,000 lbs. per diem. The want of coke in Canada, be it observed, does not oppose an obstacle to the successful prosecution of iron-works. Ours is a country of rich forests 270,000 square miles in extent. Sweden smelts her iron with charcoal only, and sells it to England for a paying price; the English convert it into steel and send it to other countries. Other European countries use charcoal, notwithstanding the general scarcity and dearness of wood in Europe."

It appears also that "no country could compete with us in the show of woods, and particularly of the kinds used in ship-building, including in the estimate all the various species. In this class are embraced, moreover, all the products of the chase and the fisheries, in which departments the Gulf, and the vast territories of the Saguenay and the North-West, place us beyond competition, if not as producers, at least as proprietors of the finest field for production, in the whole world." The hints derived from an inspection of the raw material used by cabinet makers and carpenters among European nations, suggest very extensive alterations in the mode of getting out timber in our Canadian Forests, which deserve special rotice.

"In lumbering, as the making of timber is termed in Canada, just that amount of intelligence is brought into action, which is required for the squaring of the logs, and the sawing of them into the planks of commerce. None of that skill of woodcraft is exercised which turns to the best and most profitable account the various species, by attending to their several degrees of adaptation to the mechanic arts, and to the preparation to be expended on them to make them fit for market. As before observed, two things only are known, square timber and the plank three inches thick. A more recondite study of the application of timber to the mechanic arts, would instruct us in the fact, that there are conditions of length, girth, and diameter required in those arts, by the influence of which the square log of 50 feet long by 20 inches square, and plank of 12 feet by 10 inches, lose their intrinsic value as compared with that higher value which is derivable from compliance with those conditions. How many are the trees left to rot in the forest because they are not reducible to a saw log of the standard measure, or a square stick of the required dimensions : which, trimmed to another form, would in other markets bear a greater value, though diminished in volume.

Of more than sixty principal species of timber which we possess, we make profitable use of scarcely ten, the rest are left to absolute decay. In Europe the birds'-eye maple is considered as equal to the most precious of the woods used in cabinet-work. It is indeed hardly attainable, and when found, it bears a higher price than mahogany. From this cause arises the dearness of all the articles made of maple in Parisian cabinet-work, the finest in the world."

Our agricultural productions when compared with those of other countries placed us on a level with the foremost : " our grain won the admiration of all who saw it." The absence of Hemp, Flax and Tobacco, however, was particularly noticed in the Canadian section, and our climate and soil were thought to furnish very favourable conditions for the cultivation of those valuable articles. It is not perhaps generally known by those who expressed surprise at the absence of Tobacco, that the late spring frosts to which our climate is subject. render the growth of Tobacco an expensive and very hazardous experiment. Where labour is very dear and sowing time very transient, it becomes a mere matter of calculation how far the growth of Tobacco may be made remunerative. It has often succeeded admirably in the western peninsula, but the occurrence of late frosts has not unfrequently destroyed the crops over wide areas and discouraged the cultivation of this important narcotic. Hemp and Flax give better promise of remunerative returns, and will no doubt soon form an important article of Canadian production.

37

38

Our castings did not meet with much favour, and the reasons may be drawn from the following observations by Mr. Taché :

"What lightness is found in the railings, the iron seats, &c., of the English manufacture of the Coalbrookdale Company in Shropshire, and how cheap also are the articles? The reason is plain, the purchaser has not to pay for a lot of useless iron."

"What elegance there is in the stoves and other articles of French manufacture, from the blast furnaces of the Marquis de Vogué of France? These designs of hunting and historical scenes are bas-reliefs of art, and the articles are not dearer on that account, because the material is not wasted; and as to the casting, the beautiful costs no more than the most deformed piece that ever was moulded. This is now generally understood; and in England where art is less perfect than in France and Belgium, the proprietors of foundries endeavour to procure artists from those two countries. A French sculptor, M. Geneste, is at this moment, in the receipt of a salary of £2000 per annum from an English manufacturer."

"The art of combining the useful with the agreeable is the climax of material progress. The study of the beautiful in art, is, to the intellectual man, what the study of truth is to his moral existence."

From many admirable inventions and applications which commend themselves to the attention of Canadians, and which are specially noticed with that object by Mr. Taché, we select some which appear likely to meet with adoption and favour. A smoke consuming coal grate, which is in the shape of an endless chain, and uncoils as the coal is consumed, thus combining advantages of health and economy. Α machine by M. Chevalier, which by means of an endless steel wire adapted to pullies, saws with the greatest regularity the hardest stone, as quartz, granite, and even crystal. Two machines by M. Sautreuil, of Léchamp; one for preparing flooring boards by a single stroke, the other a planing machine, for smoothing timber for building purposes, on four sides at once. Messrs. Irey and Roly, of Paris, have introduced caoutchouc as a material for springs in all their machines. In the manufacture of chemical matches, for the production of an instantaneous light, Austria employs not less than 20,000 persons, and the highest price for round matches is only one penny per thousand. Mr. Quinti, of Vienna, showed how by interrupting the current by non-conductors, two communications may be transmitted simultaneously in opposite directions by the same wire. The preservation of food by the perfect exclusion of external air is easily accomplished by the immersion of game, or other meats, in a warm solution of gelatine. The celebrated Russia Leather is tanned with the decoction of willow bark, and impregnated with an oil extracted from the bark of the bouleau. A curious result of the artificial preparation of a valuable pigment is shown in the manufacture of Ultramarine. The nat-

## REVIEWS-REPORT OF THE SMITHSONIAN INSTITUTION. 39

tural mineral used to cost £75 per pound, and no more than four pounds were used in Europe in a year; now Europe manufactures and consumes 5,000,000 lbs. per annum, at a cost of one shilling per pound. One of the active principles in opium having been artificially produced there is no doubt but that quinine and other valuable medicinal agents will be prepared on a large and cheap scale in the laboratory. Vegetables may be prepared, for keeping by exposure to hot air and powerful compression, so that 1200 lbs. of dried vegetables may be packed into a space little exceeding a cube yard; but 1200 lbs. of dried vegetables represent 8000 lbs. in their natural condition, which would require nearly forty cubic yards to contain them. The allied armies in the Crimea were provided with vegetables thus prepared to the extent of 42,000,000 rations. M. Coignet, of St Denis, exhibited a stone consisting of coal ashes and quick lime; or of sand, small shingle and lime: it is run like grouting. We may here observe that this method of building has long been practised in Amerca and even in the neighbourhood of Toronto.

It is unnecessary to advert to the "Sketch of the Geology of Canada," by Sir W. Logan and Mr. Hunt, or to the beautiful geological map accompanying the sketch, which are together appended to Mr. Taché's report, as these admirable and instructive illustrations of our mineral wealth have already been noticed in the Canadian Journal (new series, vol. i, p. 379.) We shall draw this brief summary of Mr. Taché's report to a close with a quotation from M. Fresca's work on the Exhibition; deeming it more satisfactory to receive and accept the testimony of a distinguished foreigner, than to express the favourable opinions of our great success at Paris which the perusal of Mr. Taché's report create.

"Canada," says M. Fresca, "is a land of hope not likely to be disapointed. Active, intelligent, and enterprising beyond all other nations, which equally abound in the elements of industral production, she claims and demands our attention."

Н. Ү. Н.

The Tenth Annual Report of the Smithsonian Institution for the year 1855. Washington, 1856.

To such of our readers as are unacquainted with the origin and operation of this splendid establishment, the following brief notice may not be unacceptable:

## 40 BEVIEWS-BEPORT OF THE SMITHSONIAN INSTITUTION.

Hugh Smithson, from whom the institution derives its name, was a relative of the Duke of Northumberland. He was much devoted to physical science, and at Oxford, where he graduated, enjoyed the reputation of being the best chemist in the university. He was a cosmopolitan in his views, and used to express himself to the effect that the man of science belongs exclusively to no country; that the world is his country and all men are his countrymen. It was, it is believed, at one time his intention to leave his property to the Royal Society of London, for the promotion of science, but in consequence of a misunderstanding with the council of the society, he changed his mind and left it to his nephew, and, in case of the death of that relation without issue, to the United States of America, to found the institution which now bears his name.

In 1829 Smithson died, leaving his fortune, £120,000, in case of the death of his nephew, to whom it was first bequeathed, to found at Washington, under the name of the Smithsonian Institution, an establishment for the *increase* and *diffusion* of knowledge among men.

In 1838, the nephew having died, the money was paid over by the English Court of Chancery to the Agent appointed by the Government of the United States; and eight years afterwards, in 1846, an Act was passed through Congress for the establishment of the Smithsonian Institution.

By this Act the immediate government of the institution devolved upon the Board of Regents consisting of the following 15 members:

The Vice-President of the United States, the Chief Justice of the Supreme Court, the Mayor of the City of Washington, ex-officio; three members of the Senate, to be appointed by the President thereof; three members of the House of Representatives, appointed by the Speaker; six persons chosen from the citizens at large by joint resolution of the Senate and House, two of whom shall be members of the National Institute, and the other four inhabitants of states, and no two from the same state.

With a view of carrying the wishes of the testator into effect the Secretary, Professor Henry, was empowered to draw up a programme for the organization of the institution, which was presented in his first Annual Report to the Board of Regents and adopted by them in 1847.

As this programme is presented in the report before us we are enabled to give some extracts which serve to exhibit the principles that guide the governing body, as well as the mode of carrying the objects of the institution into effect.

"General considerations which should serve as a guide in adopting a plan of organization.

(1). Will of Smithson. The property is bequeathed to the United States of America to found at Washington, under the name of the SMITHSONIAN INSTITU-TION, an establishment for the increase and diffusion of knowledge among men.

(2). The bequest is for the benefit of mankind. The Government of the United States is merely a trustee to carry out the design of the testator.

(3). The institution is not a national establishment, as is frequently supposed, but the establishment of an individual, and is to bear and perpetuate his name.

(4). The objects of this institution are, 1st., to increase, and 2nd, to diffuse, knowledge among men.

(5). These two objects should not be confounded with one another. The first is to enlarge the existing stock of knowledge by the addition of new truths; and the second, to disseminate knowledge, thus increased, among men.

(6). The will makes no restriction in favor of any particular kind of knowledge; hence all branches are entitled to a share of attention.

(13). It should be recollected that mankind in general are to be benefited by the bequest, and that, therefore, all unnecessary expenditure on local objects would be a perversion of the trust.

(14). Besides the forgoing considerations, deduced immediately from the will of Smithson, regard must be had to certain requirements of the Act of Congress establishing the institution. These are, a library a museum, and a gallery of art, with a building on a liberal scale to contain them."

In order to carry out the two leading objects of the will of Mr. Smithson, the *increase*, namely, and the *diffusion* of knowledge, the same report recommends the following plans:

To *increase* knowledge one means proposed is to stimulate men of talent to make original researches by offering suitable rewards for memoirs containing new truths. The memoirs thus obtained are to be published in a series of volumes, and entitled Smithsonian Contributions to Knowledge.

Among the various objects of research named for which pecuniary appropriations may be made are included, a system of meteorological observations for solving the problem of American storms; Explorations in Natural History and Geology; Magnetic and Topographical Surveys; the solution of various experimental problems; and Statistical, Historical and Ethnological enquiries.

To promote the *diffusion* of knowledge the two leading means suggested are the publication of periodical reports on the progress of different branches of knowledge, and the publication occasionally of separate treatises.

For the preparation of these reports it is proposed that men

## 42 BEVIEWS-REPORT OF THE SMITHSONIAN INSTITUTION.

eminent in the respective branches be employed, that they be furnished with journals and other necessary publications, and that they be paid a certain sum for their labors.

In virtue of the Act of Congress, the Secretary and his assistants, during the session of Congress, will be required to illustrate new discoveries in science and to exhibit new objects of art ; distinguished individuals will also be invited to give lectures on subjects of general interest.

On the occasion of the meeting of the Regents in 1847, it was resolved to divide the income into two equal parts; one to be appropriated to increase and diffuse knowledge agreeably to the scheme above given; and the other part to be appropriated to the formation of a library and a collection of objects of nature and of art.

This resolution was, however, rescinded at the meeting of January, 1855, when it was determined that

"The annual appropriations should be apportioned specially among the different objects and operations of the institution, in such manner as might, in the judgment of the Regents, be necessary and proper for each, according to its intrinsic importance, and a compliance in good faith with the law."

Admirably adapted as the foregoing scheme would seem to be for carrying out bona fide, the design of the founder, efforts have been made by some persons to divert from their legitimate channel the funds destined for cosmopolitan purposes, and to expend them on objects of a comparatively local character The good sense and honorable feeling of the nation have, however, triumphed, and will, it is hoped, insure the permanence of the institution on its present footing. The mode of procedure adopted by the Regents in conducting the affairs of the institution having been brought under the notice of Congress in 1855, the matter was referred to a Special Committee of the House of Representatives and to the Judiciary Committee of the Senate. In reporting subsequently on the matter the Judiciary Committee unanimously approved of the acts of the Regents in construing the law of Congress, in interpreting the will of Smithson, and in what they had done in the way of increasing and diffusing knowledge among men.

In the verdict of the Judiciary Committee we find the following language :

(Referring to the legacy). "It is not bequeathed to the United States to be used for their own benefit and advantage only, but in trust to apply to the increase and diffusion of knowledge among mankind generally, so that other men and other nations might share in its advantages as well as ourselves."
Again, in reference to the proposed application of the funds to the formation of a library, the Judiciary Committee go on to say:

"Such an application of the funds could hardly be regarded as a faithful execution of the trust; for the collection of an immense library at Washington would certainly not tend to increase or diffuse knowledge in any other country, not even among the countrymen of the testator; very few even of the citizens of the United States would receive any benefit from it.

" This is the construction which the Regents have given to the Acts of Congress, and in the opinion of the committee, it is the true one, and, acting under it, they have erected a commodious building, given their attention to all the branches of science mentioned in the law, to the full extent of the means afforded by the fund of the institution, and have been forming a library of choice and valuable books, amounting already to more than fifteen thousand volumes. The books are, for the most part, precisely of the character calculated to carry out the intentions of the donor of the fund, and of the Act of Congress. They are chiefly composed of works published by or under the auspices of the numerous institutions of Europe which are engaged in scientific pursuits, giving an account of their respective researches and of new discoveries whenever they are made. These works are sent to the Smithsonian Institution in return for the publications of this institution which are transmitted to the learned societies and establishments abroad. The library thus formed, and the means by which it is accomplished, are peculiarly calculated to attain the objects for which the munificent legacy was given in trust to the United States. The publication of the results of scientific researches made by the institution is calculated to stimulate Ameriean genius, and at the same time enable it to bring before the public the fruits of its labors. And the transmission of these publications to the learned societies in Europe, and receiving in return the fruits of similar researches made by them, gives to each the benefit of the increase of knowledge which either may obtain, and at the same time diffuses it throughout the civilized world. The library thus formed will contain books suitable to the present state of scientific knowledge, and will keep pace with its advance; and it is certainly far superior to a vast collection of expensive works, most of which may be found in any public library, and many of which are mere objects of curiosity or amusement, and seldom, if ever, opened by any one engaged in the pursuit of science."

The Judiciary Committee conclude their report in the following terms :

"From the views entertained by the committee, after an impartial examination of the proceedings referred to, the committee have adopted the language of the resolution, 'that no action of the Senate is necessary and proper in regard to the Smithsonian Institution; and this is the unanimous opinion of the committee."

Having then briefly considered the origin, proposed objects and mode of action of this magnificent establishment, it remains for us to examine from the report for the year 1855 how far the proposed objects are in course of accomplishment.

The following are the principal contents of the report of the Regents for 1855;

# 44 BEVIEWS-BEPORT OF THE SMITHSONIAN INSTITUTION.

The Report of the Secretary to the Board of Regents; the Report of the Assistant Secretary and Curator; Reports of sub-committees relative to expenditure; Journals of meetings of the board; outlines of several lectures delivered in the rooms of the institution; directions to meteorological observers and various reports and suggestions relative to meteorological observations; correspondence relative to Ethnological and Topographical researches; and, finally, a long and able report on the present condition of the science of galvanism, by Professor Müller, of Freiburg, and translated from the German by Mr. Baker, of the Coast Survey.

# SECRETARY'S REPORT.

Among the memoirs which, in accordance with the announcement in the Secretary's Report, form the eighth volume of the Smithsonian Contributions are the following: along with others, by Major B. Alvord, and Dr. Joseph Jones; and a record of Auroral phenomena, by P. Force:

(1). On the progress of information and opinion respecting the archaeology of the United States, by Samuel F. Haven, Librarian of the American Antiquarian Society.

(2). A paper on the recent secular period of the Aurora Borealis, by Professor Olmstead.

One useful function of the Smithsonian Institution is that of effecting literary and scientific exchanges between individuals and societies. The extent of their operations in this department may be judged of by the fact that in the year 1855, 8585 packages for distribution passed through the hands of the institution.

The Smithsonian agency is not confined to the transmission of works from the United States, but is extended to those of Canada and Central and South America, and its foreign relations embrace every part of the civilized world. It brings into friendly correspondence cultivators of original research the most widely separated, and emphatically realizes the idea of Smithson, that " the man of science is of no country;" that " the world is his country, and all mankind his countrymen."

The system of exchange has found favor with foreign governments, and the Smithsonian packages are now admitted into all parts to which they are sent, without detention and free of duty.

# METEOROLOGY.

Since the publication of the former report an arrangement has been made with the Commissioner of Patents, by which the system of Meteorological observations established under the direction of the institution will be extended, and the results published more fully than the Smithsonian in some will allow.

With respect to the complaints that have been made that but few of the materials collected have been published, the report remarks, "It is more important that the information should be reliable than that it should be quickly published," and "what may be lost by delay is more than compensated by the precision and value of the results.

The reduction of the meteorological observations have been continued by Professor Coffin. He has completed the discussion of all the records for 1854, and those of 1855 as far as they have been sent in.

#### LIBRARY.

It is the present intention of the Regents to render the Smithsonian library the most extensive and perfect collection of Transactions and scientific works in this country, and this it will be enabled to accomplish by means of its exchanges, which will furnish it with all the current journals and publications of societies. The Institution has already more complete sets of transactions of learned societies than are to be found in the oldest libraries in the United States.

#### MUSEUM.

It is no part of the plan of the institution to form a Museum merely to gratify the curiosity of the casual visitor to the Smithsonian building, but it is the design to form complete collections in certain branches, which may serve to facilitate the study and increase the knowledge of natural history and geology.

With respect to the condition of the Museum, the report asserts that no collection of animals in the United States, nor indeed in the world, can even now pretend to rival the richness of this Museum in specimens which tend to illustrate the natural history of North America.

In the report of Professor Baird, the Assistant-Secretary, many details are given relative to the additions to the Museum. These additions have been made in great measure through the agency of the government exploring expeditions, and partly also through that of individuals under the orders of the institution.

### LECTURES.

The titles of the lectures, of which the substance is given in the volume before us, are as follows:

(2). A course of lectures on Marine Algæ, by W. H. Harvey, of the University of Dublin.

(2). Natural History as applied to farming and gardening, by Rev. J. G. Morris of Baltimore.

(3). Insect instincts and transformations, by the same.

(4). On oxygen and its combinations, by Professor Chase. of Brown University

(5). On meteoric stones, by Lawrence Smith, of the University of Louisville, Ky

(6). On planetary disturbances, by Professor Snell, of Amherst College.

The first lecture, by the Rev. Mr. Morris, on natural history as applied to farming and gardening, will be read with peculiar interest at the present time, when attention has been so much attracted to insect ravages on the corn crops. One practical evil, spoken of by the lecturer, arising from ignorance of the habits of insects, is that farmers and gardeners, by destroying one class of noxious animals,

# 46 REVIEWS-REPORT OF THE SMITHSONIAN INSTITUTION.

expose themselves to the ravages of more numerous and destructive creatures, whose numbers, the first, if suffered to live, would have kept within bounds. Speaking of one kind of moth, peculiarly hurtful to the vineyards in France, and of what may be done to check the evil if the habits of the creature be understood, he states that in twelve days from twenty to thirty women and children destroyed upwards of forty millions of eggs that would have been hatched in a few days. From the sketch of this lecture given, we are led greatly to regret that the abstract should not have had a greater space allotted to it than five pages.

LECTURE ON METEORIC STONES, BY DR. J. L. SMITH.

The lecturer distinctly maintains the lunar organ of meteoric stones. The discussion which, even in its abridged form, occupies twenty-four pages, is concluded in the following terms:

"To sum up the theory of the lunar origin of meteorites, it may be stated that "the moon is the only large body in space of which we have any knowledge, "possessing the requisite conditions demanded by the physical and chemical pro-"perties of meteorites; and that they have been thrown off by volcanic action, "(doubtless long since extinct) or some other disruptive force, and encountering "no gaseous medium of residence, reached such a distance as that the moon ex-"ercised no longer a preponderating attraction, the detached fragment possessing "an orbital motion and an orbital velocity, which it had in common with all parts of "the moon, but now more or less modified by the projectile force and new condi-"tion of attraction in which it was placed with reference to the earth, acquired "an independent orbit more or less elliptical. This orbit, necessarily subject to "great disturbing influences may sooner or later cross our atmosphere and be "intercepted by the body of the globe."

The lecture of Professor Snell is an able popular exposition of the subject of planetary disturbances.

## METEOROLOGY.

Of the matter contained in the present volume, that of the greatest importance on account of its immediate connection with a great scientific movement now in progress in Canada, is the body of directions for the meteorological observations adopted by the Smithsonian Institution. These instructions are well worthy of the study of all persons interested in this class of research.

Following the directions to observers is an account of a series of observations carried on, chiefly for the purpose of ascertaining the duration of thunder claps.

The Report of Professor Müller on galvanism, extending as it does through upwards of 100 closely printed pages, puts any attempt at analysis in our limited space utterly out of the question; we can only, therefore, refer our readers, for more ample details, to the pages of the work.

In laying down for the present the report of the Smithsonian Institution, (and it is with no little regret that we lay it down,) we derive our chief consolation from the recollection that it is not a solitary work, but one of a series, and that we may look forward to a renewal on each succeeding year of the enjoyment we have found in the perusal of the volume that we have just closed.

G. T. K.

# SCIENTIFIC AND LITERARY NOTES.

### GEOLOGY AND MINERALOGY.

#### FOSSILS FROM ANTICOSTI.

During a recent visit to the Museum of the Geological Survey in Montreal, we were much gratified by the inspection of a fine collection of fossils, just received by Sir William Logan, from the Island of Anticosti. The greatest praise is due to Mr. Richardson, by whom, in the short space of a few months, this really mag. nificent collection was obtained. A preliminary examination by Professor Hall, of Albany, and Mr. Billings, the palæontologist attached to the Survey, has shewn the existence of a great number of new Brachiopods and other types-some, indeed, of a character at present altogether problematical. Amongst other facts of interest brought to light by the collection, we may mention the simultaneous occurrence in one of the Anticosti beds, of many well-marked forms belonging to both the Lower and Upper divisions of the Silurian series : a phenomenon not hitherto observed, or at least to a similar extent, in American rocks-the line of demarcation between the Upper and Lower Silurians of the Western World, being, as a general rule, very strongly pronounced. The lowest of the observed beds in Anticosti itself, belongs to the Hudson River Group; but the Sillery formation (the next in an ascending order) so largely developed along the Southern shores of the St. Lawrence, appears to be entirely wanting. Geologists may look forward with much interest, to the results of Professor Hall's detailed examination of this important addition to our knowledge of Palæozoic forms.

ASAPHUS LATIMARGINATUS.

### [A. Canadensis—E. J. C.]

In the Canadian Journal for September of last year (vol. 1, p. 482), we called attention, under the name of Asaphus Canadensis, to a new form of Trilobite, from Whitby, in Canada West. Quite recently, we have received a letter from Professor Hall, in which that able paleeontologist suggests to us that the Trilobite in question is probably his Asaphus latimarginatus. Professor Hall states that the Museum of the Geological Survey of Canada has lately received some very perfect specimens of that species from the neighbourhood of Whitby; and he kindly promises us a drawing and revised description of his original species, for an ensuing number of the Journal. The only figures of Asaphus latimarginatus that we have had an opportunity of examining, consist merely of two more or less imperfect caudal shields given in the first volume of Hall's Palæontology of New York. Neither thorax nor buckler has, we believe, been hitherto figured or described at least beyond the brief description given in our note in the number of the original name of A. latimarginatus, as applied by Prof. Hall to the species founded on the two imperfect caudal shields figured by him in his Palæontology, must, of course, take the place of A. Canadensis, notwithstanding the appropriateness of the latter. Up to the present time, indeed, it is only in Canada that anything like complete specimens have been met with. The following is a description of the form to which our original remarks applied :

Cephalic shield pointed anteriorly, and in its general outline closely resembling that of  $Asaphus platycephalus^*$ , but with the posterior angles terminating in horns<sup>†</sup> which extend downwards to the bottom of the fourth thoracic segment. Facial sutures united in front at the extreme anterior margin of the buckler, and terminating as in A. platycephalus about midway between the glabella and the angles of the head-shield. Glabella very feebly raised; broad, and somewhat squared above; but without furrows of any kind. Eyes apparently as in A. platycephalus, but much destroyed in all the specimens examined. For dimensions, see below.

Thorax with eight segments. Pleuræ somewhat sabre-shaped (the curve upwards<sup>‡</sup>); grooved to about half their length from the axis outwards, and then crossed obliquely by a curvilinear ridge: the points of the pleuræ beyond the ridge, delicately striated.

Caudal shield with well developed axis: the axis tapering, and terminating rather abruptly before reaching the extremity of the pygidium; number of the rings not observable in the specimens examined.§ Pleuræ 14 in number, without grooves or ridges; bent downwards abruptly near the striated margin into which they merge. The lower ones, almost vertical.

Whole surface of the trilobite finely punctured, except at the striated limb. The punctures on the pleuræ, larger and farther apart than those on the axis. Also of a crescented or semi-circular form, with the convex and more deeply indented side turned inwards:

Relative (approximate) dimensions:—Assumed length of Buckler =1. Glabella, length =  $\cdot$  812. Thorax, length =  $\cdot$  875. Pygidium, length =  $1 \cdot 06$ . Middle lobe of Thorax, bread h =  $\cdot$  50 to  $\cdot$  60. Outer lobes (each) breadth =  $\cdot$  70. The small breadth of the middle lobe in relation to the side lobes, as compared with Asaphus platycephalus, appears to be of some importance, unless it be a mere sexual

<sup>·</sup> Isotelus gigas, Auct.

<sup>+</sup> This part of the head-shield is very obscure in the specimens hitherto examined. We were led at first to believe that the angles were rounded.

<sup>&</sup>lt;sup>‡</sup> This, however, is only to be seen when the pleuræ have become accidentally separated to a certain extent from one another.

<sup>§</sup> Since the above description was written, the son of His Excellency the Governor General, has kindly submitted to us some specimens obtained by him personally from the Whitby quarries. In one of these, the pygidium of a young individual, fourteen rings may be counted in the axis.

difference. Where, however, the pleuræ are bent, the length of the side lobes can rarely be estimated with any great exactness.

The average adult size of these trilobites appears to be about  $4\frac{1}{2}$  inches in length, by about 3 inches in breadth; but, judging from isolated fragments, larger individuals no doubt occur. Many of the Whitby specimens, at the same time, are much below the above dimensions. Most of them are converted into iron pyrites. The *Asaphus Barrandi* of Hall appears to be a closely related species.

#### FOSSILS FROM ALTERED ROCKS IN EASTERN MASSACHUSETTS.

A very interesting discovery of a trilobite—a species of Paradoxides—in the metamorphic rocks of Quincy and Baintree, about ten miles South of Boston, has just been announced to the scientific world, by Professor W. B. Rogers. The true place of these rocks, hitherto of uncertain paleozoic range, would thus appear to belong to quite the base of the Silurian series: at least if the trilobite in question be really a paradoxides—in which case, it will also be of interest, as constituting the first true species of that genus met with in American rocks since the announcement of Green's debatable *Paradoxides Harlani* in 1832. Full particulars of this discovery will be found in the last October number of the Edinburgh New Philosophical Journal; and in the Proceedings of the Natural History Society of Boston, for the same month.

#### BURR-STONE.

A curious deposit of Burr-stone, constituting a vein of considerable thickness, has lately been discovered by Sir William Logan, in the gneiss of Chatham, in Canada East. The stone, probably a siliceous deposit from heated waters, occurs, according to Sir William, in close association with several complicated veins of igneous rock of at least three different periods of formation. As the stone is of excellent quality, and readily obtainable, the discovery—apart from the scientific interest belonging to the mode of occurrence of the deposit—is one of no little importance. Specimens may be seen in the Museum of the Geological Survey at Montreal.

#### RED OXIDE OF COPPER.

Mr. James Gilbert, lately returned from California, has presented to the Institute, some specimens of red copper ore from the Arizona mines, 110 miles S. E. of Fort Yunia, and about 35 miles from the River Gila. As samples, the specimens are extremely rich, being almost free from rock matter. They contain small strings of native copper, from which the Cu<sup>2</sup>O has evidently been derived; and by a further process of alteration, the ore is converted externally, into malachite, The occurrence of red copper in California has not hitherto been announced in any of our treatises on Mineralogy. We are ignorant of its geological associations,

#### VANADINITE.

In the last number of the *Journal*, (vol. 1, page 553), an analysis, by Rammelsberg, of Vanadinite from Windisch-Kappel, was given; the results of which lead to the inference that VO<sup>3</sup> and PO<sup>5</sup> are isomorphous. Adolf Kengott, (in Poggendorff's Annalen, 1856, No. 9), has subjected this analysis to a very elaborate discussion, in which he seeks to maintain that the loss of 3.21 per cent. therein exhibited, must be due to some cause other than accidental. To account for this loss, he assumes the original existence in the mineral of the hypothetical com-VOL. II.—D

pound  $VO^5$ . Rammelsberg's analysis gave 17.41 per cent of  $VO^3$ : a value corresponding to 20.31 per cent of  $VO^5$ . In this manner the total results of the analysis are brought up to 99.69; and the isomorphism of Vanadinite with Pyromorphite satisfactorily explained. Before this view can be received, however, it will be for the chemist to determine if there be any real grounds for the assumption of the existence of this higher oxygen compound. So far as present researches go, the tendency of vanadic acid,  $VO^3$ , would appear to be altogether towards reduction. The question, however, here, is not the conversion of  $VO^3$  into  $VO^5$ , but the reverse: a process which we might readily conceive to take place, were the existence of the latter compound allowed to be probable.

E. J. C.

### THE BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

CHELTENHAM, 6th August, 1856.

After the requisite preliminary business, conducted by the General Committee of the Association, and including the reading of the Report of the Council, and of that of the Kew Committee, the body of members assembled to witness the resignation of the Chair by the Duke of Argyle, to his successor, Professor Daubeny, and to hear the President's Address. On this occasion the occupation of the Chair of the British Association by one not only distinguished as a Chemist, but by one who is no less eminent as a Botanist, gave a new character to the Presidential Address. After some preliminary remarks of a personal nature, Dr. Daubeny proceeded with his address, from which we have only room for a brief selection of passages of special interest. Referring to the British Association as alike valuable as an efficient instrument for the furtherance of scientific objects, and as a model after which other associated scientific bodies have been organized, the President thus proceeded:

It is rather remarkable that the first idea of an Association of such a kind should have suggested itself only a year after death had deprived us of our three most distinguished philosophers :- for who had we then left to compare with Davy for the brilliancy and importance of his discoveries ; with Young for the singular union of almost universal acquirements with admirable powers of invention; and with Wollaston for an acuteness of mental vision, which gave him the same advantage in the pursuits of science which the naturalist, armed with a microscope has over the unassisted observer ? Just as in the animal economy the vis medicatrix naturæ sometimes makes an extraordinary effort to repair the damage inflicted by injury or disease, so it would seem as if Science, conscious of the loss she had sustained in the almost simultaneous extinction of her three brightest luminaries. endeavoured to make good the deficiency by concentrating into one focus those that yet remained, to light her onwards on her path. At any rate, the progress which the Natural Sciences have made since that period, although doubtless attributable to several concurrent causes, is a fact which must not be overlooked in estimating the services rendered by this Association to the cause of human advancement; nor can I in any better manner point out its value than by bringing before your notice a few of the additions to our knowledge which have been made since I last addressed you.

Beginning then with Chemistry, as the subject with which I am most familiar, let me remind you, that at a period not much more remote than the one alluded to, all of it that could be quoted as really worthy the name of a science was comprehended within the limits of the mineral kingdom. Here at least the outline had been traced out with sufficient precision-the general laws established on a firm basis-the nomenclature framed with logical exactness-the facts consistent with each other, and presented in a scientific and luminous form. Thus a philosopher, like Sir Humphrey Davy, who had contributed in so eminent a degree to bring the science into this satisfactory condition, might, at the close of his career, have despaired of adding anything worthy of his name to the domain of chemistry, and have sighed for other worlds to subdue. But there was a world almost as little known to the chemists of that period as was the Western Hemisphere to the Macedonian Conqueror, -a World comprising an infinite variety of important products, called into existence by the mysterious operation of the vital principle, and therefore placed, as was imagined, almost beyond the reach of experimental research. This is the new World of Chemistry, which the Continental philosophers in the first instance, and subsequently those of our own country, have during the last twenty years been busy in exploring, and by so doing have not only bridged over the Gulf which had before separated by an impassable barrier the kingdoms of inorganic and of organic nature, but also have added provinces as extensive and as fertile as those we were in possession of before, to the partrimony of Science,

It is indeed singular, that whilst the supposed elements of mineral bodies are very numerous, the combinations between them should be comparatively few; whereas amongst those of vegetable and animal origin, where the ultimate elements are so limited in point of number, the combinations which they form appear almost infinite. Carbon and hydrogen, for instance, constitute, as it were, the keystone of every organic fabric; whilst oxygen, nitrogen, and less frequently sulphur and phosphorus, serve almost alone to build up their superstructure. And yet what an infinity of products is brought about by ringing the changes upon this scanty alphabet! Even one series of bodies alone, that known by the name of the Fatty Acids, comprises several hundred well-ascertained combinations, founded however upon a single class of hydro-carbons or compound radicals, in which the carbon and hydrogen stand to each other in equal atomic proportions, and are in each case acidified by the same number of equivalents of oxygen. These acids are all monobasic, or combine with only one proportion of base; but add to any one of them two equivalents of carbonic acid, and you obtain a member of a second series, which is bibasic, or is capable of forming two classes of salts. The above therefore constitute a double series, as it were, of organic acids, the members of which are mutually related in the manner pointed out, and differ from each other in their mode of combining according to the relation between their respective elements. But already, by the labours of Hofmann and of other chemists, two other double series of acids, the one monobasic, the other bibasic, mutually related exactly in the same manner as those above, have been brought to light ; each series no doubt characterized by an equally numerous appendage of alcohols, of æthers, and of aldehydes, to say nothing of the secondary compounds resulting from the union of each of these bodies with others.

Hence the more insight we obtain into the chemistry of organic substances the more we become bewildered with their complexity, and in investigating these phe-

nomena, find ourselves in the condition of the explorer of a new continent, who. although he might see the same sun over his head, the same ocean rolling at his feet, the same geological structure in the rocks that were piled around him, and . was thus assured that he still continued a denizen of his own planet, and subject to those physical laws to which he had been before amenable, yet at every step he took was met by some novel object, and startled with some strange and portentous production of Nature's fecundity. Even so the chemist of the present day, whilst he recognizes in the world of organic life the same general laws which prevail throughout the mineral kingdom, is nevertheless astonished and perplexed by the multiplicity of new bodies that present themselves, the wondrous changes in them resulting from slight differences in molecular arrangement, and the simple nature of the machinery by which such complicated effects are brought about. And as the New World might never have been discovered, or, at all events, would not have been brought under our subjection, without those improvements in naval architecture which had taken place prior to the age of Columbus, so the secrets of organic chemistry would have long remained unelicited, but for the facilities in the methods of analysis which were introduced by Liebig. Before his time the determination of the component elements of an organic substance was a task of so much skill as well as labour, that only the most accomplished analysts-such men, for instance, as my lamented friend Dr. Prout in this country, or as the great Berzelius in Sweden-could be depended upon for such a work; and hence the data upon which we could rely for deducing any general conclusions went on accumulating with extreme slowness. But the new methods of analysis invented by Liebig have so simplified and so faciliated the processes, that a student, after a few months' practical instruction in a laboratory, can, in many instances, arrive at results sufficiently precise to be made the basis of calculation, and thus to enable the master mind, which is capable of availing itself of the facts before it, to breathe life into these dry numerical details, -- just as the sculptor, by a few finishing stokes, brings out the expression of the statue, which has been prepared for him by the laborious chiselling of a number of subordinate workmen. And as the established laws and institutions of the Old World have been modified-may I not say in some instances rectified ?---by the insensible influence of those of the New, so have the principles that had been deduced from the phenomena of the mineral kingdom undergone in many instances a correction from the new discoveries made in the chemistry of the animal and vegetable creation. It was a great step indeed in the progress of the science, when Lavoisier set the example of an appeal to the balance in all our experimental researches, and the Atomic Theory of Dalton may be regarded as the necessary, although somewhat tardy, result of the greater numerical precision thus introduced. But no less important was the advance achieved, when structure and polarity were recognized as influencing the condition of matter; and when the nature of a body was felt to be determined, not only by the condition of its component elements, but also by their mutual arrangement and collocation-a principle which, first illustrated amongst the products of organic life, has since been found to extend alike to all chemical substances whatever.

Formerly it had been the rule to set down the bodies which form the constituents of the substances we analyzed, and which had never yet under our hands undergone decomposition, as elementary; but the discovery of cyanogen in the first instance, and the recognition of several other compound radicals in organic chemistry more lately, naturally suggest the idea that many of the so-called elements of

inorganic matter may likewise be compounds, differing from the organic radicals above mentioned merely in their constituents being bound together by a closer affinity. And this conjecture is confirmed by the curious numerical relations subsisting between the atomic weights of several of these supposed elements; as, for example, between chlorine, bromine and iodine : an extension of the grand generalization of Dalton, which, although it was unforeseen by the Founder of the system, and therefore, like Gay-Lussac's Theory of Volume, might very possibly have been repudiated by him, had it been proposed for his acceptance, will be regarded by others as establishing, in a manner more conclusive than before, the soundness of his antecedent deductions. What, indeed, can be a greater triumph for the theorist, than to find that a law of nature which he has had the glory of establishing by a long and painful process of induction, not only accommodates itself to all the new facts which the progress of discovery has since brought to light, but is itself the consequence of a still more general and comprehensive principle, which philosophers, even at this distance of time, are still engaged in unfolding ?

But passing over speculations which have not as yet received the general assent of chemists, let me advert to others of an older date, possessing, as I conceive, the strongest internal evidence in their favour, which the case admits, from the harmony they tend to introduce into the chaos of facts which the late discoveries in organic chemistry have brought to light. Amongst these, one of the most generally received, and at the same time one of the most universal application, is that which represents the several combinations resulting from organic forces, as being put together according to a particular model or type, which impresses upon the aggregate formed certain common properties, and also causes it to undergo change most readily, through the substitution of some other element in the place of one of those which already enters into its constitution. And this principle, having been established with regard to one class of bodies, has since been extended to the rest; for it now begins to be maintained, that in every case of chemical decomposition a new element is introduced in the place of one of those which constituted a part of the original compound, so that the addition of a fresh ingredient is necessarily accompanied by the elimination of an old one. The same doctrine, too, has even been extended to the case of combination with a body regarded as elementary, for here also the particles are considered as being in a state of binary combination one with the other, owing perhaps to their existing in opposite electrical conditions, and therefore possessing for each other a certain degree of chemical affinity. Thus, when we unite hydrogen with oxygen, we substitute an atom of the latter for one of the former, previously combined with the same element.

\* To the microscope we owe all that is as yet known with respect to the reproductive process in cryptogamous plants, which are now shown to possess a structure analogous to that of flowering ones in respect to their organs of reproduction; not, indeed, as Hedwig supposed, that parts corresponding to stamens and pistils in appearance and structure can be discovered in them, but that as the primary distinction of sexes seems to run throughout the Vegetable Kingdom, new parts are superadded to a structure common to all as we ascend in the scale of creation, until from the simple cell, which, in consequence of some differences of structure, to our eyes inappreciable, appears to exercise in one case the function of the male, in another of the female, as is found the case in certain of the Confervæ, we arrive

\*

at length at the complicated machinery exhibited in flowering plants, in which the cell containing the fecundating principle is first matured in the stamen, and afterwards transmitted, through an elaborate apparatus, to the cells of the ovule, which is in like manner enveloped in its matrix, and protected by the series of investing membranes which constitutes the seed-vessel. Thus, as Goethe long ago observed, and as modern physiologists have since shown to be the case, the more imperfect a being is, the more its individual parts resemble each other-the progress of development, both in the Animal and Vegetable Kingdoms, always proceeding from the like to the unlike, from the general to the particular. But whilst the researches of Brown and others have shown that there is no abrupt line of division in the Vegetable Kingdom, and that one common structure pervades the whole, the later inquiries of Suminski, Hofmeister, Unger, Griffith, and Henfrey, have pointed out several curious and unlooked-for analogies between plants and animals. I may mention, in the first place, as an instance of this analogy between plants and animals, the existence of moving molecules, or phytosperms, in the antheridia of ferns and other Cryptogams, borne out, as it has been in so remarkable a manner, by the almost simultaneous observations of Bischoff and Meissner on the egg, confirmatory of those formerly announced by Barry and Newport, and by the researches of Suminski, Thuret, and Pringsheim, with respect to the ovule of plants. I may refer you also to a paper read at the last Meeting of the Association, by Dr. Cohn, of Breslau, who, in bringing this subject before the Natural History Section, adduced instances of a distinction of sexes which had come under his observation in the lower Algæ. In like manner a curious correspondence has been traced between the lower tribes of animals and plants, in the circumstance of both being subject to the law of what is called alternate generation. This consists in a sort of cycle of changes from one kind of being to another, which was first detected in some of the lower tribes of animals; a pair of insects, for example, producing a progeny differing from themselves in outward appearance and internal structure, and these reproducing their kind without any renewed sexual union,-the progeny in these cases consisting of females only. At length, after a succession of such generations, the offspring reverts to its primæval type, and pairs of male and female insects, of the original form, are reproduced, which complete the cycle, by giving rise in their turn to a breed presenting the same characters as those which belong to their own progenitors. An ingenious comparison had been instituted by Owen and others between this alternation of generations in the animal, and the alternate production of leaves and blossoms in the plant; but the researches to which I especially allude have rendered this no longer a matter of mere speculation or inference, inasmuch as they have shown the same thing to occur in ferns, in lycopodia, in mosses, nay, even in the confervæ. We are indebted to Prof. Henfrey for a valuable contribution to our Transactions in 1851 on these subjects, given in the form of a Report on the Higher Cryptogamous Plants; from which it at least appears that the proofs of sexuality in the Cryptogamia rank in the same scale, as to completeness, as those regarding flowering plants did before the access of the pollen tubes to the ovule had been demonstrated. Indeed, if the observations of Pringsheim with respect to certain of the Algæ are to be relied upon, the analogy between the productive process in plants and animals is even more clearly made out in these lower tribes than it is in those of higher organization. It also appears that the production in ferns and other Acrogens of what has been callled a pro-embryo; the evolution of antheridia and archegonia, or of male and female organs, from the former; and the generation from the archegonia

of a frond bearing spores upon its under surface, is analogous to what takes place in flowering plants in general; where the seed, when it germinates, produces stem, roots, and leaves; the stem for many generations gives rise to nothing but shoots like itself; until at length a flower springs from it, which contains within itself for the most part the organs of both sexes united, and, therefore, occasions the reproduction of the same seed with which the chain of phenomena commenced. This is the principle which a learned Professor at Berlin has rather obscurely shadowed out in his treatise on the Rejuvenescence of Plants, and which may perhaps be regarded as one, at least, of the means by which Nature provides for the stability of the forms of organic life she has created, by imparting to each plant a tendency to revert to the primeval type.

To the elder De Candolle we are also indebted for some of our most philosophical views with respect to the laws which regulate the distribution of plants over the globe,-views which have been developed and extended, but by no means subverted, by the investigations of subsequent writers; amongst whom Sir Charles Lyell, in his 'Principles of Geology,' and the younger De Candolle, a worthy inheritor of his father's reputation, in his recently published work on Botanical Geography, have espescially signalized themselves. But it is to the late Prof. Edward Forbes, and to Dr. Joseph Hooker, that we have principally to attribute the removal of those anomalies, which threw a certain degree of doubt upon the principles laid down by De Candolle in 1820, in his celebrated article on the Geography of Plants, contained in the 'Dictionnaire des Sciences Naturelles,' where the derivaion of each species from an individual, or a pair of individuals, created in one particular locality, was made the starting point of all our inquiries. These anomalies were of two different kinds, and pointed in two opposite directions: for we had in some cases to explain the occurrence of a peculiar Flora in islands cut off from the rest of the world, except through the medium of a wide intervening ocean; and in other cases to reconcile the fact of the same or of allied species being diffused over vast areas, the several portions of which are at the present time separated from each other in such a manner, as to prevent the possibility of the migration of plants from one to the other. Indeed, after making due allowances for those curious contrivances by which Nature has in many instances provided for the transmission of species over different parts of the same continent, and even across the ocean, and which are so well pointed out in De Candolle's original essay, we are compelled to admit the apparent inefficiency of existing causes to account for the distribution of the larger number of species; and must confess that the explanation fails us often where it is most needed, for the Compositæ in spite of those feathery appendages they possess, which are so favorable to the wide dissemination of their seeds, might be inferred, by their general absence from the fossil Flora, to have diffused themselves in a less degree than many other families have done. And on the other hand, it is found, that under existing circumstances, those Compositæ, which are disseminated throughout the area of the Great Pacific, belong in many cases to species destitute of these auxiliaries to transmission. But here Geology comes to our aid; for by pointing out the probability of the submergence of continents on the one hand, and the elevation of tracts of land on the other, it enables us to explain the occurrence of the same plants in some islands or continents now wholly unconnected, and the existence of a distinct Flora in others too isolated to obtain it under present circumstances from without. In the one case we may suppose the plants to have been distributed over the whole area before its several parts became

disunited by the catastrophes which supervened; in the other, we may regard the peculiar Flora now existing as merely the wreck, as it were, of one which once overspread a large tract of land, of which all but the little patch on which it is now ' found had been since submerged. Upon this subject our opinions may in some measure be swayed by the nature of the conclusion we arrive at with respect to the length of time during which seeds are capable of mantaining their vitality; for if after remaining for an indefinite period in the earth they were capable of germinating, it would doubtless be easier to understand the revival, under favorable circumstances, of plants which had existed before the severance of a tract of land from the continent in which they are indigenous. An inquiry has accordingly been carried on for the last fifteen years under the auspices of, and with the aid of funds supplied by, this Association, the results of which, it is but fair to say, by no means corroborate the reports that had been from time to time given us with respect to the extreme longevity of certain plants, exemplified, as it was said, in the case of the mummy-wheat and other somewhat dubious instances; inasmuch as they tend to show, that none of the seeds which were tested, although they were placed under the most favorable artificial conditions that could be devised, vegetated after a period of forty-nine years; that only twenty out of 288 species did so after twenty years; whilst by far the larger number had lost their germinating power in the course of ten. These results, indeed, being merely negative, ought not to outweigh such positive statements on the contrary side as come before us recommended by respectable authority, such, for instance, as that respecting a Nelumbium seed, which germinated after having been preserved in Sir Hans Sloane's Herbarium for 150 years ; still, however, they throw suspicion as to the existence in seeds of that capacity of preserving their vitality almost indefinitely, which alone would warrant us in calling to our aid this principle in explaining the wide geographical range which certain species of plants affect.

But if this be allowed, what limits, it may be asked, are we to assign to the changes which a plant is capable of undergoing,—and in what way can we oppose the principle of the transmutation of species, which has of late excited so much attention, and the admission of which is considered to involve such startling consequences? I must refer you to the writings of modern physiologists for a full discussion of this question. All that I shall venture to remark is, that had not Nature herself assigned certain boundaries to the changes which plants are capable of undergoing, there would seem no reason why any species at all should be restricted

within a definite area, since the unlimited adaptation to external conditions which it would then possess might enable it to diffuse itself throughout the world, as easily as it has done over that portion of space within which it is actually circumscribed. Dr. Hooker instances certain species of Coprosma, of Celmisia, and a kind of Australian Fern, the Lomaria procera, which have undergone such striking changes in their passage from one portion of the Great Pacific to another, that they are scarcely recognizable as the same, and have actually been regarded by preceding botanists as distinct species. But he does not state that any of these plants have ever been seen beyond the above-mentioned precincts; and yet if Nature had not imposed some limits to the suscptibility of change, one does not see why they might not have spread over a much larger portion of the earth, in a form more or less modified by external circumstances. The younger De Candolle, in his late admirable treatise already referred to, has enumerated about 117 species of plants which have been thus diffused over at least a third of the surface of the globe, but these apparently owed their power of transmigration to their insusceptibility of change, for it does not appear that they have been much modified by the effect of climate or locality, notwithstanding the extreme difference in the external conditions to which they were subjected. On the other hand, it seems to be a general law, that plants whose organization is more easily affected by external agencies become from that very cause, more circumscribed in their range of distribution; simply because a greater difference in the circumstances under which they would be placed brought with it an amount of change in their structure which exceded the limits prescribed to it by Nature. In short, without pretending to do more than to divine the character of those impediments, which appear ever to prevent the changes of which a plant is suceptible from proceeding beyond a certain limit, we seem to catch a glimpse of a general law of Nature, not limited to one of her kingdoms, but extending everywhere throughout her jurisdiction,-a law, the aim of which may be inferred to be that of maintaining the existing order of the universe, without any material or permanent alteration, throughout all time, until the fiat of Omnipotence has gone forth for its destruction. The will which confines the variations in the vegtable structure within a certain range, lest the order of creation should be disturbed by the introduction of an indefinite number of intermediate forms is apparently the same in its motive as that which brings back the celestial luminaries to their original orbits, after the completion of a cycle of changes induced by their mutual perturbations; it is the same which says to the ocean. Thus far shalt thou go, and no further; and to the winds, Your violence, however apparently capricious and abnormal, shall nevertheless be constrained within certain prescribed limits-

> Ni faciat, maria et terras cœlumque profundum, Quippe ferant rapidi secum, verrantque per auras.

The whole, indeed, resolves itself into, or at least is intimately connected with, that law of symmetry to which Nature seems ever striving to conform, and which possesses the same significance in the organic world, which the law of definite proportions does in the inorganic. It is the principle which the prophetic genius of Goethe had divined, long before it had been proved by the labours of physiologists to be a reality, and to which the poet attached such importance, that the celebrated discussion as to its merits which took place in 1830 between Cuvier and Geoffry St. Hilaire so engrossed his mind, as to deprive him, as his biographer informs us, of all interest in one of the most portentous political events of modern days which waa enacting at the very same epoch,—I mean the subversion of the Bourbon dynasty.

It is, indeed, not less calculated to subserve to the gratification of our sense of the Beautiful than to provide against too wide a departure from that order of creation which its great Author has from the beginning instituted; and, as two learned . Professors of a sister kingdom have pointed out in Memoirs laid before this Association, and have since embodied in a distinct treatise, manifests itself not less in the geometrical adjustment of the branches of a plant, and of the scales of a fir-apple -nay even, as they have wished to prove, in the correspondence between the form of the fruit and that of the tree on which it grows-than in the frequent juxtaposition of the complimentary rays of the spectrum, by which that harmony of colour is produced in Nature which we are always striving, however unsuccessfully, to imitate in Art. The law, indeed, seems to be nothing else than a direct consequence of that unity of design pervading the universe, which so bespeaks a common Creator-of the existence in the mind of the Deity of a sort of archetype, to which His various works have all, to a certain extent, been accommodated ; so that the earlier forms of life may be regarded as types of those of latter creation, and the more complex ones but as developments of rudimentary parts existing in the more simple.

I might be disposed to claim for the recent investigations of botanists some share in fixing the relative antiquity of particular portions of the globe, for from the Floras they have given us of different islands in the Great Pacific, it would appear that the families of plants which characterize some groups are of a more complicated organization than those of another. Thus, whilst Otaheite chiefly contains Orchids, Apocyneæ, Asclepiadeæ, and Urticeæ; the Sandwich Islands possess Lobeliaceæ and Goodenoviæ; and the Galapagos Islands, New Zealand and Juan Fernandez, Compositæ, the highest form, perhaps, of dicotyledonous plants. In deducing this consequence, however, I am proceeding upon a principle which has lately met with opposition, although it was formerly regarded as one of the axioms in Geology. Amongst these, indeed, there was none which a few years ago seemed so little likely to be disputed as that the classes of animals and vegetables which possessed the most complicated structure were preceded by others of a more simple one; and that when we traced back the succession of beings to the lowest and the earliest of the sedimentary formations, we arrived at length at a class of rocks, the deposition of which must be inferred, from the almost entire absence of organic remains, to have followed very soon after the first dawn of creation. But the recognition of the footsteps and remains of reptiles in beds of an earlier date than was before assigned to them, tended to corroborate the inferences which had been previously deduced from the discovery, in a few rare instances, in rocks of the secondary age, of mammalian remains; and thus has induced certain eminent geologists boldly to dispute, whether from the earliest to the latest period of the earth's history any gradation of beings can in reality be detected. Into this controversy I shall only enter at present, so far as to point out an easy method of determining the fact, that organic remains never can have existed in a particular rock, even although it may have been subjected to such metamorphic action as would have obliterated all traces of their presence. This is simply to ascertain that the material in question is utterly destitute of phosphoric acid; for inasmuch as every form of life appears to be essentially associated with this principle, and as no amount of heat would be sufficient to dissipate it when in a state of combination, whatever quantity of phosphoric acid had in this manner been introduced into the rock, must

have continued there till the end of time, notwithstanding any igneous operations which the materials might have afterwards undergone. But as the discovery of very minute traces of phosphoric acid, when mixed with the other ingredients of a rock, is a problem of no small difficulty, an indirect method of ascertaining its presence suggested itself to me in some experiments of the kind which I have instituted, namely, that of sowing some kind of seed, such for instance as barley, in a sample of the pulverized rock, and determining whether the crop obtained yielded more phosphoric acid than was present in the grain, it being evident that any excess must have been derived from the rock from which it drew its nourishment. Should it appear by an extensive induction of particulars, that none of the rocks lying at the base of the Silurian formation, which have come before us, contain more phosphoric acid than the minute quantity I detected in the slates of Bangor and Llanberris, which were tested in the above manner, it might perhaps be warrantable hereafter to infer that we had really touched upon those formations, that had been deposited at a time when organic beings were only just beginning to start into existence, and to which therefore, the term Azoic, assigned to these rocks by some of the most eminent of our geologists, might not be inappropriate. The proofs of the former extension of glaciers in the Northern hemisphere, far beyond their actual limits, tend also to complicate the question which has at all times so much engaged the attention of cosmogonists with respect to the ancient temperature of the earth's surface, compelling us to admit that, at least during the latter of its epochs, oscillations of heat and cold must have occurred, to interfere with the progress of refrigeration which was taking place in the crust. On the other hand, facts of an opposite tendency, such as the discovery announced at our last meeting by Capt. Belcher, of the skeleton of an Ichthyosaurus in lat. 77°, and of the trunk of a tree standing in an erect position in lat. 75°, have been multiplying upon us within the same period; inasmuch as they appear to imply, that a much higher temperature in former times pervaded the Arctic regions that can be referred to local causes, and therefore force upon us the admission, that the internal heat of the nucleus of our globe must at one time have influenced in a more marked manner than at present the temperature of its crust.

Twenty years ago it was thought necessary to explain at our meetings the character and objects of this Association, and to vindicate it from the denunciations fulminated against it by individuals, and even by parties of men, who held it up as dangerous to religion, and subversive of sound principles in theology. Now so marked is the change in public feeling, that we are solicited by the clergy, no less than by the laity, to hold our meetings within their precincts; and we have never received a heartier welcome than in the city in which we are now assembled, which values itself so especially, and with such good reason, on the extent and excellence of its educational establishments. It begins, indeed, to be generally felt, that amongst the faculties of the mind, upon the development of which in youth success in after life mainly depends, there are some which are best improved through the cultivation of the Physical Sciences, and that the rudiments of those sciences are most easily acquired at an early period of life. That power of minute observation inquiry-that tact and sagacity in deducing inferences from evidence short of demonstration, which the Natural Sciences more particularly promote, are the fruits of early education, and acquired with difficulty at a later period. It is during child-

hood, also, that the memory is most fresh and retentive and that the nomenclature of the sciences, which, from its crabbedness and technicality, often repels us at a more advanced age, is acquired almost without an effort. Although, therefore it can hardly be expected that the great schools in the country will assign to the Natural Sciences any important place in their systems of instruction until the Universities for which they are the seminaries set them the example, yet I cannot doubt but that, the signal once given, both masters and scholars will eagerly embrace a change so congenial to the tastes of youth, and so favorable to the development of their intellectual faculties. And has not, it may be asked, the signal been given by the admission of the Physical Sciences into the curriculum of our academical education? I trust that this question may be answered in the affirmative, if we are entitled to assume that the recognition of them which has already taken place will be constantly followed up by according to them some such substantial encouragement as that which has been afforded hitherto almost exclusively to classical literature. Our ability to accomplish this, with the means and appliances at our command, does not, I think, admit of dispute. All, therefore, that seems wanted, is, on the one hand, a more equal distribution of the existing emoluments between the several professions, and on the other, the admission of the claims of the sciences received into our educational system to share in the emoluments which up to this time, have been monopolized by the Classics. And, as it is far from my wish to curtail the older studies of the University of their proper share of support-fo. who that has passed through a course of academical study can be insensible of the advantages he has derived from that early discipline of the mind which flows from their cultivation ?--- I rejoice to think, that when the Legislature shall have completed the removal of those restrictions which have hitherto prevented us in many instances from consulting the claims of merit in the distribution of our emoluments, there will be ample means afforded for giving all needful encouragement to the newly-recognized studies, without trenching unduly upon that amount of pecuniary aid which has been hitherto accorded to the classics. In anticipation of which change, I look forward with confidence to the day when the requirements at Oxford in the department of Physical Sciences will become so general and so pressing, that no institution which professes to prepare the youth it instructs for academical competition will venture to risk its reputation by declining to admit these branches of study into its educational courses.

ON THE THEORY OF COMPOUND COLOURS WITH REFERENCE TO MIXTURES OF BLUE AND YELLOW LIGHT. BY MR. J. C. MAXWELL.

When we mix together blue and yellow paint, we obtain green paint. This fact is well known to all who have ever handled colours; and it is universally admitted that blue and yellow make green. Red, yellow, and blue being the primary colours among painters, green is regarded as a secondary colour, arising from the mixture of blue and yellow. Newton, however, found that the green of the spectrum was not the same thing as the mixture of two colours of the spectrum, for such a mixture could be separated by the prism, while the green of the spectrum resisted further decomposition. But still it was believed that yellow and blue would make a green, though not that of the spectrum. As far as I am aware, the first experiment on the subject is that of M. Plateau, who, before 1819, mode a disc with alternate sectors of Prussian blue and gamboge, and observed that, when spinning, the resultant tint was not green, but a neutral grey, inclining

sometimes to yellow or blue, but never to green. Prof. J. D. Forbes, of Edinburgh, made similar experiments in 1849, with the same result. Prof. Helmholtz, of Königsberg, to whom we owe the most complete investigation on visible colour, has given the true explanation of this phenomenon. The result of mixing two coloured powders is not by any means the same as mixing the beams of light which flow from each separately. In the latter case we receive all the light which comes either from the one powder or the other. In the former, much of the light coming from one powder falls on a particle of the other, and we receive only that portion which has escaped absorption by one or other. Thus, the light coming from a mixture of blue and yellow powder, consists partly of light coming directly from blue particles or yellow particles, and partly of light acted on by both blue and yellow particles. This latter light is green, since the blue stops the red, yellow, and orange, and the yellow stops the blue and violet. I have made experiments on the mixture of blue and yellow light-by rapid rotation, by combined reflection and transmission, by viewing them out of a focus, in stripes, at a great distance, by throwing the colours of the spectrum on a screen, and by receiving them into the eye directly; and I have arranged a portable apparatus by which any one may see the result of this or any other mixture of the colours of the spectrum. In all these cases blue and yellow do not make green. I have also made experiments on the mixture of coloured powders. Those which I used principally were "mineral blue" (from copper) "and chrome yellow." Other blue and yellow pigments gave curious results, but it was more difficult to make the mixtures. and the greens were less uniform in tint. The mixtures of these colours were made by weight, and were painted on discs of paper, which were afterwards treated in the manner described in my paper 'On Colour as perceived by the Eye, in the Transactions of the Royal Society of Edinburgh, Vol. xx1., Part 2. The visible effect of the colour is estimated in terms of the standard-coloured papers: --vermilion (V,) ultramarine (U,) and emerald green (E.) The accuracy of the results, and their significance, can be best understood by referring to the paper before mentioned. I shall denote mineral blue by B, and chrome yellow by Y; and B. Ya means a mixture of three parts blue and five parts yellow.

| B4             | Y4                 | 100 | =   | 15       | 1      | 40        |       | 56         |
| B              | $\overline{Y}_{5}$ | 100 | =   | 22       | -2     | 44        |       | 64         |
| B <sub>2</sub> | Y <sub>6</sub>     | 100 | =   | 35       | -10    | 51        |       | 76         |
| B,             | Y <sub>7</sub>     | 100 | =   | 64       | -19    | 64        |       | 109        |
| •              | Y.                 | 100 | =   | 180      | -27    | 124       |       | 277        |

--The columns  $V_{\cdot}$ ,  $U_{\cdot}$ ,  $E_{\cdot}$  give the proportions of the stardard colours which are equivalent to 100 of the given colour; and the sum of  $V_{\cdot}$ ,  $U_{\cdot}$ ,  $E_{\cdot}$  gives a co-efficient, which gives a general idea of the brightness. It will be seen that the first admixture of yellow *diminishes* the brightness of the blue. The negative values of  $U_{\cdot}$ indicate that a mixture of  $V_{\cdot}$ ,  $U_{\cdot}$ , and  $E_{\cdot}$  cannot be made equivalent to the given colour. The experiments from which these results were taken had the negative

values transferred to the other side of the equation. They were all made by means of the colour-top, and were verified by repetition at different times.

" ON SOME DICHROMATIC PHENOMENA AMONG SOLUTIONS, AND THE MEANS OF REPRESENT-ING THEM," BY DR. GLADSTONE.

This paper was an extension of Sir John Herschel's observations on dichromatism, that property whereby certain bodies appear of a different colour according to the quantity seen through. It depends generally on the less rapid absorption of the red ray as it penetrates a substance. A dichromatic solution was examined by placing it in a wedge-shaped glass-trough, held in such a position that a slit in a window-shutter was seen traversing the varying thicknesses of the liquid. The diversely coloured line of light thus produced was analyzed by a prism; and the resulting spectrum was represented in a diagram by means of coloured chalks on black paper, the true position of the apparent colours being determined by the fixed lines of the spectrum. In this way the citrate and comenamate of iron, sulphate of indigo, litmus in various conditions, cochineal, and chromium, and cobalt salts where examined and represented. Among the more notable results were the following :- A base, such as chromic oxide, produces very nearly the same spectral image with whatever acid it may be combined, although the salts may appear very different in colour to the unaided eye. Citrate of iron appears green, brown, or red, according to the quantity seen through. It transmits the red ray most easily, then the orange, then the green, which covers the space usually occupied by the yellow; it cuts off entirely the more refrangible half of the spectrum. Neutral litmus appears blue or red, according to the strength or depth of the solution. Alkalies cause a great development of the blue ray; acids cause a like increase of the orange, while the minimum of luminosity is altered to a position much nearer the blue. Boracic acid causes a development of the violet. Alkaline litmus was exhibited so strong that it appeared red, and slightly acid litmus so dilute that it looked bluish purple; indeed, on account of the easy transmissibility of the orange ray through an acid solution, the apparent paradox was maintained that a large amount of alkaline litmus is of a purer red than acid litnus itself. Another kind of dichromatism was examined, dependent not on the actual quantity of coloured material, but on the relative proportion of the solvent. Diagrams of the changing appearances of sulphocyanide of iron, of chloride of copper, and of chloride of cobalt were exhibited.

# "ON A METHOD OF DRAWING THE THEOBETICAL FORMS OF FARADAY'S LINES OF FORCE WITHOUT CALCULATION," BY MR. J. C. MAXWELL.

The method applies more particularly to those cases in which the lines are entirely parallel to one plane, such as the lines of electric currents in a thin plate, or those round a system of parallel electric currents. In such cases, if we know the forms of the lines of force in any two cases, we may combine them by simple addition of the functions on which the equations of the lines depend. Thus the system of lines in a uniform magnetic field is a series of parallel straight lines at equal intervals, and that for an infinite straight electric current perpendicular to the paper is a series of concentric circles whose radii are in geometric progression. Having drawn then two sets of lines on two separate sheets of paper and laid a third piece above, draw a third set of lines through the intersections of the first and second sets. This will be the system of lines in a uniform field disturbed by an electric current. The most interesting cases are those of uniform fields disturbed by a small magnet. If we draw a circle of any diameter with the magnet for centre, and join those points in which the circle cuts the lines of force, the straight lines so drawn will be parallel and equi-distant, and it is easily shewn that they represent the actual lines of force in a paramagnetic, diamagnetic, or erystallized body, according to the nature of the original lines, the size of the circle, &c.

#### ON THE FORM OF LIGHTNING.

Mr. J. Nasmyth read a paper to the effect that the form of lightning as exhibited by nature was an irregular curved line, shooting from the earth below to the cloud above, and often continued from the cloud downwards again to some distant point of the earth; and this appearance was the result of the rapidly-shooting point of light, which constituted the true-lightning, leaving on the eye the impression of the path it traced. These views led to much discussion in the Section.

(To be continued.)

### AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

The Tenth Meeting of the American Association for the Advancement of Science was opened at Albany, in the Capitol of the State of New York, on the 20th of August, by Professor James B. Hall. A deputation from Montreal was introduced to the association on the following day, and Principal Dawson of McGill College, in the name of the deputation, communicated the invitation to the Association,—which at a subsequent meeting was accepted,—that the next meeting should be held in Montreal.

The American Association is still on a much smaller scale than its British prototype; and in some respects presents characteristic differences. The arrangements of business, which are left in the British Association exclusively in the hands of the Central Committee, were at Albany repeatedly made the subject of discussion by the whole body; and a good deal of time was lost in debates in general meeting, upon questions of order and constitutional forms, little calculated to interest those who had been attracted from a distance by the desire to listen to the communications of the distinguished representatives of American Science assembled on the occasion. Another characteristic, which could scarcely fail to strike those who are familiar with the proceedings of the British Association. was the absence of that numerous body of youthful aspirants for a place among the ranks of the Scientific Legion, which constitutes so valuable a feature in the Sections at Home. Already, chairs in the Colleges of England, Scotland, and Ireland, are filled by those who owed their first introduction to the Scientific world to the Sections of the British Association; and not the least of the benefits traceable to that institution pertain to this important feature of its organization. which has been so employed as to invite the younger students of Science into the arena, and stimulate them to compete with those whose rank has long been established by universal consent. The American Association on the contrary seems chiefly composed of the veterans of Science; nor was there wanting some appearance of an apprehension of any greater infusion of the popular element, such as the influence of the political institutions of that Country on all large and some-

what miscellaneous assemblies may perhaps fully justify. But whatever may be the effects of this absence of the predominating element of youthful aspirants for honors in the field of Scientific adventure, the assembly of so many of the most distinguished representatives of American Scientific Veterans, was a peculiarly acceptable feature to those who were allured from other countries, by the echo of their fame. Nor must it be overlooked that in whatever other respects the popular element may work, it is scarcely possible for a warmer or more hospitable welcome to be offered any where, than that which the citizens of Albany, and the Official representatives of the State of New York, tendered to the assembled Congress of American Science, and to the visitors attracted by the justly earned reputation of its members.

The great feature of interest at this meeting was the inauguration of the Dudley Astronomical Observatory. This observatory has been founded by the liberality of some citizens of Albany, among whom Mrs. Dudley, whose name it bears, has not only contributed upwards of \$25,000 for the building and instruments but has announced a further donation of \$50,000 towards its permanent endow- . ment. The Hon. Edward Everett delivered a splendid oration on the occasion, in the presence of the Association, the dignitaries of the State, and the citizens of Albany, the venerable foundress herself occupying the seat of honour. The observatory is built in a solid and massive style, and finely situated on the brow of a hill; its erection was superintended by a committee of eminent astronomers, and the construction of the instruments was entrusted to Dr. GOULD, who has accepted the appointment of Director. At a meeting in Section, Dr. Gould described in detail the new instruments. The minor instruments have been received, and the Observatory has been fitted up with these and others lent by Prof. BACHE from the Coast Survey, but the reception of the larger instruments will be delayed for a few weeks longer. The Transit circle, combining in one the Transit telescope and meridian circle, was ordered from PISTOR and MARTIUS, the celebrated manufacturers of Berlin, by whom the new instrument at Ann Arbor was made. A number of improvements have been introduced in the Albany instruments, not perhaps all absolutely new, but an eclectic combination of late adaptations with new improvements. Dr. Gould made a distinction of modern astronomical intruments into two classes, the English and the German. The English is the massive type; the German, light and airy. The English instrument is the instrument of the engineer; the German, the instrument of the artist. In ordering the instruments for the Albany Observatory, the Doctor had endeavoured to combine the two, with, however, a preference to the German type. The circle is three feet in diameter, graduated to intervals of two minutes, and read by micrometers to tenths of seconds. The microscopes are four in number, and are not carried by moveable frames, but are imbedded in the piers. The piers themselves completely surround the circle so as to eliminate the effect of changes of temperature by radiation. The tube of the telescope is eight feet in length, and the object glass is eight inches clear aperture. The glass was made by Chance, of Birmingham, and ground by Pistor himself. The eye-piece, in addition to the diaphragm, is furnished with two micrometers, one for vertical, the other for horizontal motion, the use of these being for the circumpolar stars, whose motion is too slow for registration by the Chronographic method. One principle has been adhered to in the whole of the instrumental arrangements, namely: that every error is capable of being determined in two independent ways.

Much trouble was experienced in securing a good casting for the steel axis of the instrument. Three were found imperfect under the lathe, and the fourth was chosen, but even then, the pivots were made in separate pieces, which were set in very deeply, and welded.

Dr. GOULD said he would have preferred a smaller instrument, in which the facilities of manipulation would have been greater, but was hampered by one proviso, upon which the Trustees of the institution insisted—that this should be the biggest instrument of its kind, and the instruction was obeyed. He had been requested by the gentlemen who had this enterprise in charge, to suggest, as a mark of respect to a gentleman of Albany, who was a munificent patron. of Science, that this instrument be known as the Olcott Meridian Circle. The other large instrument for the Observatory, the Heliometer, has been entrusted to an American artist, but is not yet completed. It was also announced that the American Astronomical Journal, hitherto supported at Dr. GOULD's editorship, the responsibility of its cost having been assumed by a number of gentlemen of that City.

Among the Astronomical papers read before the Association was one by Dr. PETERS on a Periodical Comet of thirteen years. This Comet was discovered by Dr. PETERS, at Naples, in 1846. He has prepared an ephemeris of the Comet from 1857 to 1860. The comet was very difficult to observe; its light was so faint in 1846 that he could not perceive it until he had reposed his eve for some seconds in darkness. Even under these circumstances he had only seen it at intervals during a period of twenty days. He had devoted some time to calculating where the comet might be looked for on its re-appearance, and had drawn lines on a map, from eight days to eight days, so that the observer would be saved much of the labor of sweeping, and the comet could readily be discovered. The probable orbit gives an ellipse of thirteen years, with a probable error of one year, so that its period might be twelve or fourteen years. In 1854, Saturn came into nearly the same position as this comet, and some uncertainty exists as to its distance, it having been difficult to ascertain whether it was nearer the interior or the exterior of that planet. Unless some accident had happened, the comet might be looked for either fifty-six days before or fifty-six days after the 15th of March, 1859. This enquiry had become of more importance since two comets pronounced periodic, those of de Vico and Brünnow, had failed to re-appear. Dr. PETERS remarked that the discovery of comets has decreased. Last year, not more than one or two were discovered. He thought this falling-off is owing partly to the fact that the award of a comet medal has been abandoned by the King of Denmark. For many years, the discoverer of any telescopic comet received a comet-medal from the King, but in 1848 the custom was abolished, and the zeal for discovery has since declined. He hoped the institution of the comet-medal would be renewed here.

Dr. Gould observed that it was not a little curious that since the establishment of the Observatory at Pultowa the realm of Denmark had contributed 200 per cent. more to the progress of astronomical science, in proportion to its population, than any other country. The comet medal, whose institution was suggested by Schumacher, continued to be awarded for fifteen years, during which period the discoveries of comets averaged five to seven per annum, and the average discover-

ies of each comet by independent observers three to four. Since it has been abolished the discoveries of comets have not averaged over three per annum, and the independent simultaneous discoveries of the same comet have become exceedingly rare.

THE UNITED STATES COAST SURVEY.

The progress of this magnificent work has furnished, as usual, many valuable results in Science since the preceding meeting of the Association; the following abstracts of the Papers read will shew how great credit is due both to the energy and skill of the conductors of this undertaking, and to the wise liberality of the Government which supports it.

"The Distribution of Terrestrial Magnetism in the United States," by Prof. Bache and J. D. Hilgard.

The magnetic observations made in connection with the Survey were scattered, at 160 different stations, along the entire sea coast, and the data were reduced to the common period of the year 1850. The line of no variation, or that passing through all the places where the magnetic needle points to the true north, intersects the coast near Ocracoke, between Cape Hatteras and Cape Fear, in a N.N.W. direction, curving gradually to the North, and passing through the middle of Lake Erie.

To the north and east of this line the declination (or variation of the compass) is to the west of north, being 6° near New York,  $10^{\circ}$  near Boston, and  $16^{\circ}$  in the eastern part of Maine. To the south and west of the line of no variation it is east of north, being 8° east along a line running directly south a little to the west of St. Louis and New Orleans,  $13^{\circ}$  near San Diego, and  $21^{\circ}$  near Cape Flattery on the western coast. The dip of the needle varies from  $75^{\circ}$  in the North eastern States to  $60^{\circ}$  along the northern shore of the Gulf of Mexico, and the horizontal force from 3.5 to 6.0 in the same regions.

SUPPLEMENT TO THE PAPER PUBLISHED IN THE PROVIDENCE PROCEEDINGS, ON THE SECULAR VARIATION IN MAGNETIC DECLINATION IN THE ATLANTIC AND GULF COAST OF THE UNITED STATES, FROM OBSERVATIONS IN THE SEVENTEENTH, EIGHTEENTH AND NINETEENTH CENTURIES, UNDER PERMISSION OF THE SUPERINTENDENT. BY CHAS. A. SCHOTT.

In a paper communicated to the Association at the Providence meeting the secular change of the magnetic declination was investigated by Mr. Schott. In the course of last summer he made some additional observations by direction of the Superintendent of the Coast Survey, and in the paper now presented the results are combined with those previously obtained. The former deductions have gain-. ed considerably in accuracy, and have received important additions. The number of stations is increased from ten to thirteen. The recent observations appear to show a slight diminution in the rate of increase of westerly declination, leading to the supposition that the inflexion in the curve representing the secular variation corresponds to about 1850. All the observations concur in placing the minimum about 1800. The present rate of increase of westerly declination is about five minutes annually along the Atlantic coast.

DISCUSSION OF THE SECULAR VARIATION OF MAGNETIC INCLINATION IN THE NORTH-EASTERN STATES. COMMUNICATED, UNDER PERMISSION OF THE SUPERINTENDENT AND AUTHORITY OF THE TREASURY DEPARTMENT, BY CHARLES A. SCHOTT.

The results are confined to the limits of 38 deg. and 44 deg. of North latitude, there being too few observations in the southern part of the United States to permit

safe inferences there. The element of magnetic dip, though less important practically than that of declination, is of value in navigation in certain latitudes, and from its connection, through Gauss' investigations, with the declination and intensity, assumes a high degree of importance. While the declination observations on this coast go back to the seventeenth century, the dip has only been accurately observed for 23 years; for the earliest observations made in 1782 were, from the imperfection of the instruments, of little value. During this period the dip has decreased, reached a minimum, and begun again to increase, so that it has been a highly interesting period for observation. The lines of equal dip have been deduced by Professor Loomis, from the observations which he had accumulated before the date of his paper. The present memoir includes additional results, and discusses 161 observations made at the different stations between Toronto on the north, and Baltimore on the south. The average probable error of the result at any one station is about one minute and six-tenths of dip, and the time of minimum dip is ascertained to be about two years and seven-tenths. This time was the year 1843, or rather the close of 1842 (1842-7). Mr. Schott points out why these results do not agree with Professor Hansteen's, who had not observations enough to determine the epoch of minimum dip with accuracy. Observations on the Western coast confirm these results for the Eastern.

ON THE CAUSE OF THE INCREASE OF SANDY HOOK. BY PROF, BACHE.

It is well known, as one of the developments of the Survey, that the Hook is gradually increasing, growing to the northward into the main ship channel. At a spot north of the Hook, where there were forty feet of water when Captain GEDNEX made his survey, in less than ten years it was nearly bare. The importance of determining the cause of this increase, as leading to the means of controlling it cannot be over estimated. The Commissioners on Harbor Encroachments had early attended to the matter and requested that the necessary observations for its investigation should be made. These were under the immediate direction of Prof-BACHE, the observations having been made by HENRY MITCHELL, one of the sub-assistants in the Coast Survey, with all desirable zeal and ability.

Various causes had been assigned for this growth from the action of the waves and the winds, sometimes on the outer side and sometimes on the inside of the Hook. The effect of the opening and closing of Shrewsbury inlet had also been insisted upon.

To examine these and other probable causes laborious observations of tides and currents had been made in the vicinity of stations which Prof. BACHE showed upon the map. Careful measurements of the low water line had also been made in connection with these observations, and with others of the force and direction of the winds. Objects easily distinguished from the sand, and of various specific gravities and shapes, had been deposited near the shore of the Hook to determine the power and direction of transportation of matter along the shores of the Hook. The results of these observations have not yet been worked out in all their detail, but the conclusions from them are perfectly safe, and are of the highest importance. Itturns out that this growth of the Hook is not an accidental phenomenon, but goes on regalarly and according to determinable laws. The amount of increase depends upon variable causes, but the general fact is that it increases year by year, and the these observations assign along both shores of the Hook, the outer one extending across the whole breadth of False Hook channel, with varying velocity, and the one

inside of the Hook extending nearly one-third of the distance across Sandy Hook Bay. These currents run to the north, during both the ebb and flood tide, with varying rates, and result from those tides directly and indirectly. The inner current is the one by which the flood and ebb tides draw, by the lateral communication of motion, the water from Sandy Hook Bay, and the outer is similarly related to those tides as they pass False Hook channel. The velocities and directions found, favor this conclusively.

An important observation for navigation results from this, for eleven hours out of the twelve, there is a northwardly current running through False Hook channel, which assists vessels entering New York harbor on the ebb tide, and is to be avoided in passing out with the ebb.

It is the conflict of these two northwardly currents outside and inside, and the deposit of the materials which they carry to the point of the Hook, which causes its. growth.

Within a century it has increased a mile and a quarter, and at about the rate of one sixteenth of a mile a year, on the average, for the last twelve years.

Flynn's Knoll, on the north side of the main ship channel, does not give way, as the point of the Hook advances. The importance of watching this movement cannot, therefore be over stated.

The mode of controlling the growth is obvious from the result obtained. The observations are still continued, to obtain the necessary numerical results.

APPROXIMATE COTIDAL LINES OF DIURNAL AND SRMI-DIURNAL TIDES OF THE COAST OF THE UNITED STATES ON THE GULF OF MEXICO-BY A. D. BACHE, SUPERINTENDENT UNITED STATES COAST SURVEY. COMMUNICATED BY AUTHORITY OF THE TREASURY DEPART-MENT.

This paper is supplementary to those on cotidal lines of the Atlantic and Pacific coasts heretofore communicated to the Association. Preparation was made at the last meeting for these conclusions by presenting the type curves of the Gulf coast The tides from Cape Florida to St. George's are of the usual type, with a large daily inequality. From St. George's to the mouth of the Mississippi they are of the single day type. Then the half-day tides reappear to extend beyond Galveston, the day tides recurring at Aransas, in Texas, and southward. When the type curves were presented, the mode of decomposing them with a diurnal and semi-diurnal wave was described. The tide stations extend along our whole coast, but observations are much wanted beyond it to complete the investigation, on the south side of the Straits of Florida, on the eastern coast of the Gulf of Mexico south of Texas, and especially between Cuba and Yucatan, at the entrance of the Gulf from the Caribbean sea.

A table of the stations at which the observations were made, of the heights of tide (rise and fall) observed, and of the half-day and day tides, was given; and another showing the period of observation and the name of the observer. The first table is represented on a diagram by which a navigator may find the rise and fall of tide approximately on any part of our Gulf coast. The least observed rise and fall is at Brazos Santiago, Texas, and is nine tenths of a foot. The greatest is at Cedar keys, Florida, and is two and a half feet. The difficulties of the problem presented by these tides are explained, removable in part by the progress of the survey of the Gulf, inherent in them in part. The labors of Mr. Pourtales and other gentlemen concerned in the discussion of these tides are acknowledged. The single-day tides have not been so elaborately discussed by former physicists or mathe-

maticians as to prepare the way fully for this work. The formula for the times given by Professor Avery in his "Tides and Waves," when compared with the observed times, differs remarkably in certain parts of the lunar month. A diagram shows the general form of the curve of interval between the moon's transit and high water. Advantage is taken of the part of the curve which changes but little in ordinate to obtain an average luni-tidal interval corresponding in kind with the number for semi-diurnal tides, known at the establishment. These tides occur about the period of greatest declination of the moon. These intervals, at greatest declination, vary greatly during the year; and the form of curve showing the annual change is presented, as deduced from observations at key West, Fort Morgan (Mobile entrance), and Galveston, as well as from San Francisco, on the Western coast, where the results are remarkably regular. These annual curves are used to deduce the average number for the interval of the daily tides from the short series of observations; the limits of uncertainty of the process are pointed out. These intervals are next turned into cotidal hours by the usual process of correcting for the difference of longitude, for transit, for depth, and by the process just described for the annual change. A table of cotidal hours for the various stations is then given. By it the cotidal lines are traced, the tide waves entering the Straits of Florida, passing through them, crossing to the entrance of the Mississippi, and passing laterally to the western coast of the peninsula of Florida from south to north, and along the southern coast of Upper Florida, along the eastern coast of Louisiana from the Southwest Pass northward, and along the coast of Mississippi. Also, into the Gulf between Southwest pass and the Rio Grande, in such a way that Galveston has, as the head of the Gulf, the latest cotidal hour. By forming groups of stations, the direction of the cotidal lines, the mean cotidal hour, and the velocity of the wave's movement are roughly determined. The difficulties of forming the groups are explained, and the general character of the results given by them are shown in a table and upon a diagram map. Upon the map also are given the cotidal hours of the stations, and the results of the grouping. Finally, from the study of the groups and their connection, the cotidal lines or the daily tides are drawn upon the map. The main cotidal hour of the northern shore of the Gulf is twenty-six hours, twenty seven occurring at the head of the bight in which Galveston lies. The twenty-five hour line appears at Cedar Keys, and touches the coast again at Brazos Santiago. Twenty-three is at the Tortugas and Key West, and nineteen at Cape Florida.

A similar course to that just described is followed in the discussion of the semi-diurnal tides. The table of stations, their positions, and the other data necessary to obtain cotidal hours is given. The progress of the semi-diurnal wave as indicated by three hours is also shown. The general motion of the wave is like that of the diurnal wave, with very characteristic peculiarities. From the line of deep water joining the Tortugas and Southwest Pass at the entrance of the Mississipi the semi-diurnal wave reaches the stations on the western coast of the Florida peninsula in this order, from south to north and west. The movement west of St. George's appears to be in the order of Pensacola, Fort Morgan and Cat Island, while for the diurnal wave it was Cat Island, Fort Morgan, Pensacola. To the westward of Southwest Pass there is a sudden increase of establishment, as if another semi-diurnal wave brought the tides there. The mean cotidal hour of the five sections west of Southwest Pass is 20 h. 6 m., while that of Southwest Pass and "three east of it is 16 h. 17 m., a difference of about four hours. This taken with

the remarks already made in regard to the appearance of two high waters in the curves for Isle Dernier and Calcasieu, indicate a system of interferences yet to be unravelled. As was the case with the diurnal wave, the stations at Isle Dernier , and Calcasieu gave cotidal hours very like those of Brazos Santiago and Aransas, and Galveston is later then either.

The differences between the cotidal hours for the diurnal and semi-diurnal tides are shown in a table. The grouping of the semi-diurnal results is next made, and the results tabulated and drawn on a diagram map. This map also shows the cotidal lines deduced. The cotidal lines of thirteen and fourteen hours only appear on the coast of the Florida Keys; that of sixteen hours is well marked, near Egmont Key (Tampa), and passes around the shore of the great Bay, between Louisiana and Florida, to near Southwest Pass. The line of eighteen hours is at the head of the heights, between St. George's and Cedar keys, and seventeen in that near Cat Island; the lines of sixteen and twenty-one have succeeded each other closely in the bay to the westward of Southwest Pass.

In comparing the two sets of cotidal lines for the diurnal and semi-diurnal waves, we find a general resemblance in the great bay between the western coast of Florida and the eastern coast of Louisiana. The lines of 24, 25 and 26 of the diurnal tide on the eastern side of the bay, corresponding generally with 16, 17 and 18 of the semi-diurnal tides and 25 and 26 hours of the diurnal tide on the western side of the bay corresponding generally to 16 and 17 of the semi-diurnal. On the southern coast of Florida, by the Keys, on the contrary the lines of 19, 20, 21, 22 and 23 hours succeed each other rapidly between Cape Florida and the Tortugas, in the diurnal series, along the same shores in the semi-diurnal tide. On the contrary on the west of southwest Pass, the lines of 26, 27 and 28 hours only occurat considerable distances in the diurnal system, while 16, 17, 18, 19, 20 and 21 occur in the same space between Southwest Pass and Brazos Santiago in the same diurnal tide.

# NOTES ON THE PROGRESS MADE IN THE COAST SURVEY, IN PREDICTION TABLES FOR THE TIDES OF THE UNITED STATES COAST, BY A. D. BACHE, SUPTD., ETC.

Communicated by authority of the Treasury Dept.

As soon as tidal observations had accumulated sufficiently to make the task **a** profitable one, I caused them to be treated, under my immediate direction, by the methods in most general acceptance. The observations at Old Point Comfort, Virginia, were among the earliest used for this purpose, and the labors of Commander Charles H. Davis, U. S. N., then an assistant in the coast survey, were directed to their reduction chiefly by the graphical methods pointed out by Mr. Whewell. This work was subsequently continued by Mr. Lubbock's method, by Mr. Henry Mitchell; and next the tides of Boston harbor were taken up as affording certain advantages in the observations themselves, which could not be claimed for those of Old Point.

The system of Mr. Lubbock is founded on the equilibrium theory, and in it the inequalities are sought by arranging the elements of the moon's and sun's motions, upon which they depend. Having obtained the coefficient of the half monthly inequality of the semi-diurnal tide at Boston, from seven years' observations, through the labors of the tidal division, and approximate corrections for the parallax and declination, I was much disappointed in attempting the verification by applying to individual tides for a year during which we had observations. There was a general agreement on the average but a discrepancy in the single cases, which was quite

unsatisfactory. Nor were these discrepancies without law, as representing their residuals by curves did not fail to show. By introducting corrections for declination and parallax of the moon increasing and decreasing, we reduced these discrepancies, but still the results were not sufficient approximations. With the numerical reductions of the observations before referred to, was commenced in 1853, under my immediate direction, by Mr. L. W. Meech, a study of the theory of the tides, directed chiefly to the works of Bernoulli, La Place, Avery, Lubbock and Whewell. The immediate object which I had in view was the application of the wave theory to the discussion of our observations. I thought that the mind of an expert mathematician, directed entirely to the theoretical portions of this work, with directionby a physicist, and full opportunities of verifying results by extended series of observations, the computations of which should be placed by others in any desired form, would give, probably, the best result in this combined physical and mathematical investigation.

The general form of the different functions expressing the tidal inequalities is the same in the different theories, and may be said on the average to be satisfactory as to the laws of change which these inequalities present. Whether we adopt, with La Place, the idea that periodical forces produce periodical effects, or with Avery, that the tidal wave arrives by two or more cauals; or with Bernoulli and Lubbock, the results of an equilibrium spheroid; or with Whewell, make a series of inequalities, semi-menstrual, parallax and declination, with different epochs, we arrive at the same general results, that the heights and times of high water may be represented by certain functions, with indeterminate co-efficients, in the form of which the theories in a general way agree. By forming equations from the observations, and obtaining the numerical values of the co-efficients by the methods used so commonly in astronomical computations, the result is accomplished.

A general consideration of the co-ordinates in space of the moon and sun, without any special theory, would lead to the same result, representing the luni-tidal interval by a series of sines and co-sines, with indeterminate co-efficients.

The grouping of the observations of one year at Boston, to apply this methodthe formation of the equations and their solution by the method of indirect elimination has been the work of Mr. R. L. Avery.

To test the co-efficients, computations, for the predicted times of the tide at Boston harbor were made for a period from March 1853, to January 1854, and from comparison of these with the observed, it appears that in twenty pairs of tides, the morning and afternoon being grouped to get rid of the diurnal inequality, there are two differences of less than two 2 m., thirteen of more than 2 m. and less than 4 m., three of more than 4 m. and less than 10 m., two of more than 10 m. The probable error of the prediction of a single pair of tides is 4.12 m. so that greater accuracy of prediction has been attained by this method from a single years's observations that was found at London bridge from a period of nineteen years.

#### LAW OF MORTALITY.

Prof. McCoy, of Albany, read a paper in which he announced the important discovery of a mathematical formula which correctly expressed the law of mortality for all ages; it was first evolved from an analysis of the Carlisle and Northampton tables, but the Professor had compared it with a large number of others and said that, "so complete is its agreement with all, that at no age does the calculated number of the living differ from the number given in the tables by a single year's mortality." The formula is, that, for the age x, the rate of mortality or the ratio of the dead to the living for that age is expressed by

 $c^x$ 

a b

where, a, b, c, are constants which differ for different tables. From this the Professor drew the following conclusions;

1. The rate of mortality invariably increases from youth to old age.

2. This rate is continually accelerated even in a higher ratio than in geometrical progression.

3. In early manhood, the rate does not differ much from a slow arithmetical progression.

4. There are no crises or elimacterics at which the chances for life are stationary or improving.

5. There are no periods of slow and rapid increase succeeding each other; but one steady, invariable progress.

6. The law, though not the rate of mortality, is the same for city and country, for healthy and unhealthy places, for every age and country and locality; and this law is that the differences of the logarithms of the rates of mortality are in geometrical progression.

#### OZONE OBSERVATION.

Prof. Rogers gave an account of some observations made by him on the existence of ozone in the atmosphere. In the first instance these were made at Boston, and he here found winds blowing from the sea heavily ozonised, while those from the land were less so; on removing, however, fifty miles inland, he found the indications of ozone apparently independent of the quarter from which the wind was blowing, and depending more on its velocity; in a calm there being but slight ozonic effect, the increase being marked with the violence of the wind. This was to have been expected from the imperfect character of the mode of observation, since the effect produced on the test paper would depend on the quantity of ozone brought in contact with it, and this of course depended on the quantity of air that passed over it in a given time. To remedy this defect, he had arranged an apparatus by which the number of cubic feet of air passing over the test paper could be measured.

Dr. Webster, of Norfolk, added an important observation, "Last year, while the yellow fever was at Norfolk and Portsmouth, I kept an ozonometer constantly exposed to the air, and never dejected ozone. This year I have used the ozonometer in the same place, and at the same period of time, and I find ozone in abundance."

THERMIC EFFECT OF THE SUN'S RAYS.

In a paper, by Mrs. Eunice Foote, some interesting results of experiments on this subject were given. The experiments were made by exposing freely to the Sun's rays a thermometer, with blackened bulb, enclosed in a glass receiver, which contained the various gases experimented on. The effect was found to be greatest of all in Carbonic Acid gas: for example, when in air the thermometer stood at 106°, in Hydrogen it stood at 104°; in Oxygen, at 108°, and in Carbonie Acid at 125°. It was also found that the thermic effect was increased in air by an increase of its density and also by an increase of the moisture in it.

(To be continued.)

MONTHLY METEOROLOGICAL REGISTER AT THE PROVINCIAL MAGNETICAL OBSERVATORY, TÓRONTO, CANÀDA WEST, OCTOBER, 1856. Latitude-43 deg. 39.4 min. North. Longitude-79 deg. 21 min. West. Elevation above Lake Ontario, 108 feet.

| Rain fell on 10 days, amounting to 5.220 inches; it was raining 50 hours and 5 minutes. |      |  |  |  |  |  |
| Most prevalent wind, W S W. Least prevalent wind, E by S.                               |      |  |  |  |  |  |
| Most windy day, the 29th day; mean miles per hour, 16.55.                               |      |  |  |  |  |  |

Least windy day, the 5th day, mean miles per hour, 0.23

Most windy hour, from 10 to 11, A. M., 29th day; velocity 31.00 miles.

There were 226 hours and 45 minutes calm.

There were 9 cloudless days in the month.

Total amount of miles of wind, 3732.10 miles, which being resolved into the Four Cardina Points, gives N 843 miles. S 371 miles, W 2270.10 miles, and E 248 miles.

Aurora Borealis visible on 5 nights.

Eclipse of the Moon on the 13th day visible.

The electric state of the atmosphere has been marked by moderate intensity.

Ozone was in moderate quantity.

# THE CANADIAN JOURNAL.

## NEW SERIES.

No. VIII.-MARCH, 1857.

# THE PRESIDENT'S ADDRESS.

BY THE HON. CHIEF JUSTICE DRAPER, C. B.

Read before the Canadian Institute, January 10th, 1857.

My first duty in assuming the Chair of the Canadian Institute, is to thank you for the honour you have done me in electing me to fill a position which has been previously occupied by men justly distinguished, and with such special claims to the honour. Without assuming a forced humility, or that tone of self-depreciation which is ever akin to vanity, I cannot but recognize my own deficiencies, and wish myself better qualified for the duties I ought to discharge. If I have felt hesitation in undertaking these duties, it is from no want of regard for the Canadian Institute, or of desire for its welfare; still less is it from undervaluing those who have assigned to me so conspicuous a place in a body associated together for objects at once so honorable, and so indispensable to the highest interests of this Province. But in accepting the office of President I comfort myself with the assurance that I am surrounded, in the Council, by those selected by you, and well qualified to relieve me of the grave responsibilities which the high aims of this Institute would otherwise impose on me; while I can only assure you that I yield to no member of this Society in earnest zeal for the promotion of its best interests, or in the high estimate of what it is capable of accomplishing for Canada.

VOL. II.-F

The Report of the Council for the year 1856, of the proceedings of the Institute, affords much reason for congratulation. The ad-' ditions to the number of its members show the increasing sense of the value of the Institute; and this conclusion is strengthened by the observation in the report, that these additions are such as give it "a Provincial rather than a local character," and entitle us to hope for a far more widely extended co-operation than we at first might have reasonably expected. In no respect, perhaps, can that co-operation be more usefully afforded than in communications on the various branches of literature, science, and art, which, read at the meetings of the Institute, may, whenever their novelty or importance justifies it, form part of the published records of our proceedings, in the Canadian Journal. Observation and experience are the sources for enlarging the extent of all our knowledge. The communication of individual observation and experience not only adds to the general mass of what is known, but it furnishes help to the attainment of further knowledge. Every phenomenon, whether the result of physical experiment, or of that class which occur independently of human agency, when properly observed and noted, promotes the knowledge of causes, and aids in the deduction of general laws. I cannot doubt that, among the members of the Institute, there are many capable of responding to the invitation of the Council in this respect, and where the capacity exists I feel less doubt that there will be a readiness shown to co-operate with those who have so strenuously laboured for our advantage, and who devote so much of their time and talents to our service. In no way can a sense of obligation to the Council of the Institute generally, or to the Editing Committee of the Canadian Journal in particular, be more fitly shown than in an endeavour to share in their labours, and to promote the objects to which they are devoted. In so doing we are, in truth, serving ourselves. The influence of science extends alike to agriculture, to commerce, to manufactures, to the administration of justice, to each art of domestic life, and to the prosperity of the Province. The comfort and enjoyment of its inhabitants are dependent on those pursuits. Every advance made in the one is of necessity a corresponding benefit to the other. The time is quickly passing by-in some parts of the Province it has already passedwhen all the farmer has to do, after exhausting one portion of his land, is, to leave it to waste, and to clear another. Such a process must very soon bring itself to an end; and those whose whole knowledge of farming has been obtained under such training stand more

#### THE PRESIDENT'S ADDRESS.

in need of guidance than the agriculturists of other countries where more advanced systems of husbandry are in vogue, even though their systems have little pretence to a scientific foundation. But now, when the necessity and value of a different mode of farming are fully felt and acknowledged, science has come to the aid of agriculture; and principles, developed and made manifest by chemical research, have been brought within the husbandman's reach.

The knowledge of what food plants require in order to attain the fullest maturity, and consequently what manures are best fitted to an exhausted soil, or to a soil incapable in its natural composition of affording that nutriment, is one of those benefits which agriculture owes to purely scientific research, and which makes the name of Liebig a household word with every farmer capable of appreciating the advantages so derived.

I am more at home in referring to the acknowledgments which are due for the assistance rendered by physical science and observation in Judicial investigations. The past year has afforded one very remarkable instance of its invaluable service in bringing to justice a criminal, whose slow but surely fatal operations on his victim's life would never have been demonstrated but for the aid of chemical analysis. There was a Nemesis in this. The murderer, who availed himself of the discoveries of chemistry—subtilely, and as he hoped so as to defy detection—to inflict death, was discovered and subjected to his well-deserved fate, through the instrumentality of that very branch of science which he had so grossly abused.

It concerns us all that physical science should unite with jurisprudence in increasing our protection against crime, by affording means, unthought-of before its aid was invoked, for the detection of the guilty. The number of criminals would be greatly reduced if there was an assured certainty that crime would be followed by detection, as well as detection by punishment. As one means of securing this I have observed the practice adopted in England, and I believe also in some other parts of Europe, of taking Photographic likenesses of persons charged with crime, and thus depriving them of the chances of escaping identification, which a change of name or of residence might afford. The A. B. of London criminal notoriety may be arrested in Liverpool and known there only as C. D.; all inquiries respecting him under the alias may be wholly unavailing, but the portrait transmitted from the police of the latter to that of the former city, removes the difficulty and puts the avenger of violated aw on the right track.

Still further: Judicial investigation into crime has been assisted by the microscope. It is stated as the result of the most careful and oft repeated examinations, that in every kind of animal the blood contains globules which constitute its colouring matter, differing in size from those of every other, and as a consequence that human blood can be distinguished accurately and certainly when examined through this instrument. By this mode a hiatus in evidence may be filled up, for the want of which a criminal might have escaped; or, on the other hand, circumstances apparently of great suspicion may be satisfactorily rebutted, and an unjustly accused individual may be saved.

I cannot refrain from recalling to you one among many instances of the discoveries of criminals effected through the aid of the microscope, in illustration of what I have said.

A box containing money had been stolen on one of the Railways in Prussia, and, after being emptied of its contents, was filled with sand and replaced on the car. The Police were at fault; the land round most of the stations in the north of Prussia is sandy, and the contents of the box seemed to afford them no clue to the place where the exchange had been made.

Professor Ehrenberg was applied to, and having procured samples of the sand along the line of the Railway, he, with the aid of the microscope, examined them, and also compared them with the sand in the box. The powerful instrument he used enabled him at once to discover the characteristic variations in the mineralogical composition and crystallization of the various specimens of disintegrated rock from the different localities. The station from whence the sand in the box had come was thus ascertained, and the conviction of the thief was the immediate consequence.

To the same professor is also due the application of the microscope for the detection of a singular literary forgery. A pretended palimpsest, purporting to be a history of some of the ancient Kings of Egypt, was submitted to him. It was clearly shown by the microscope that wherever the professedly ancient writing was crossed by that of more modern times, the ink of the old letters lay *upon* instead of *under* those of later date: precisely the reverse of what must have been the case had the palimpsest been genuine. The fraud was immediately and unanswerably exposed.

There are other topics which claim a passing attention. Among these: the proposition to establish a railway communication from Europe to India, intended for the transport of goods as well as of passengers, is of great interest, and suggests an inquiry as to the channels of former communication between Europe and the East.

According to Robertson, the Phenicians procured the products of India, brought overland, to Rhinocolura, in the Mediterranean, a port, according to the best maps I have had an opportunity of consulting, not far distant from the modern El-Arish, and conveying them by a short transport, thence to Tyre, made the latter city the great emporium of that most profitable commerce. The conquests of Alexander, and the founding of that city which still exists as an enduring monument of his far-sighted sagacity, drew commerce into a new channel, and transferred to Alexandria the trade of which the Phenicians had had the monopoly. Subsequently, a portion of this trade appears to have been carried on up the Euphrates and by land carriage to Palmyra, and thence to the Mediterranean, until the conquest of Palmyra by Aurelian destroyed this commerce. Some portion of the trade was also carried on through the Provinces which extend along the northern frontier of India, either by land carriage into the interior parts of Persia, or by means of rivers through Upper Asia to the Caspian, and thence to the Euxine sea.

It was through such channels of communication that Constantinople obtained its supply of East Indian products. The hostilities that sprang up between the Christians and the Mahommedans, almost, if not entirely, put an end to European intercourse with Alexandria, and with such parts of Syria as had been the marts of Indian commodities. At a later period Venice obtained a great control over this trade, which continued as long as Constantinople remained the capital of the Latin Empire. The restoration of the Imperial family to the throne, however, aided as it was by the Genoese, gave these in turn the advantages which the Venetians had monopolized, and the merchants of Venice were consequently driven to re-establish that commercial intercourse with Alexandria which had been so long interrupted. But the final overthrow of the Greek Empire by Mahomet II., in 1453, deprived the Genoese of their advantages and possessions both at Constantinople and in the Crimea, and again limited the introduction of the commodities of the East into Europe to purchases made in Egypt, or in certain ports in Syria, and this state of things continued until the Portuguese doubled the Cape of Good Hope, towards the close of the 15th century, and thus discovered a new route by ocean navigation to the East. This discovery, and the events consequent upon it, resulted in the almost total extinction of the commerce which Venice had so long enjoyed,

and thenceforward the trade of Europe with India was carried on by sea, though other regions still obtained supplies of Eastern products by land carriage. Of late years the overland route to India by , way of Alexandria has been again commonly used by travellers, but it has not been resorted to, at least to any considerable extent, for the conveyance of goods. Now, in addition to this route, two lines for railway communication have been suggested; one by the valley of the Euphrates, which is said to present no physical obstacles that may not readily be surmounted; the other commencing at Acre and passing by Basra, to continue along the southerly side of the Persian Gulph, and then crossing the spur of the Arabian Peninsula to Mascal, a port accessible by a short sea voyage from Bombay. This is represented as being much more direct than either of the other routes. Whether any of them will be found practicable, in a financial and commercial point of view, or in the existing state of things, and considering the character of the people through whose countries the transit is proposed, has yet to be ascertained and determined. Mahommedan antipathies to nations professing Christianity, at least to the Western powers of Europe, have doubtless greatly diminished, and when the "Infidel Soldan" disdains not to wear as a badge of honor, the emblem of the Christian Knight slaughtering the dragon, any enterprise which has no greater obstacles to contend against than religious prejudices, or the antipathies of an uncivilized against a civilized people, and which is backed by the prospect of bringing wealth in its train, need not be despaired of.

Another subject, however, more immediately interesting to us as inhabitants of the Western hemisphere, as well as subjects of the British Empire, claims attention. I allude to the projected Atlantic telegraph. Wonderful as is the application of voltaic electricity to land communication, its capability of adaptation to transmit submarine messages, which is no longer a mere matter of theory, is calculated still more to excite our admiration The nautical and engineering difficulties attending this mode of telegraphic communication have been proved to be surmountable, and the experience gained in establishing shorter lines has led to the determination to undertake this. It is gratifying to observe the unity of thought and action in reference to this great work that prevails on both sides of the Atlantic. A survey was made last summer in a steamer belonging to the United States, and soundings at intervals of about thirty miles were taken, from which it was ascertained that the greatest depth was rather less than 23 miles. Lieutenant Maury, the superintendent of the observatory at Washington, who deservedly occupies a high place among scientific men, in reporting on this survey, expresses no doubt of the ultimate success of the undertaking. "There is at the bottom of this sea between Cape Race in New-"foundland and Cape Clear in Ireland, a remarkable steppe, which "is already known as the telegraphic plateau," and extends for some 1300 miles in water so deep as to be beneath the effect of any tempest which may agitate the surface, for it has been ascertained "that the currents do not reach down to the bottom of the deep "sea, and that there are no abrading agents there, save alone the "gnawing tooth of time."

The principal difficulty anticipated was the size of the cable supposed to be necessary, not to resist the action of the sea, but to transmit messages at a speed sufficient to ensure commercial success. On this subject a paper was read in August last before the British Association for the advancement of Science, by Mr. E. O. W. Whitehouse, in which he discussed the question whether the law of the squares was applicable or not to the transmission of signals in submarine circuits; and as the result of experiments on the limit to the rapidity and distinctness of utterance attainable-his experiments reaching over wires to the length of 1020 miles-he states his conviction that " nature knows no such application of that law," and that we may shortly expect to see a cable not much exceeding in weight a ton per mile, containing three, four, or five conductors, connecting Europe with America at an expense of less than one-fourth of such a one as would be necessary if the law of the squares were held to be good in its application to submarine currents, and if the deductions as to the necessary size of that wire, based upon that law, could be proved valid. Although his positions were combated, yet the result of his views as to the necessary size of the wire seems to have been adopted, for in an extract from Lt. Maury's report it is said : "It may now be considered as a settled " principle in submarine telegraphy, that the true character of a " cable for the deep sea is not that of an iron rope as large as a "man's arm, but a single copper wire, or a fascicle of wires coated " with gutta percha, pliant and supple, and not larger than a lady's " finger," or, at any rate, than an alderman's thumb !

I have seen it stated that the manufacture of this cable is already commenced, and you are all well aware of the support to the financial part of the undertaking, promised by the British Government. It is difficult to estimate the importance of its success to the North American Provinces, whether as an element of commercial progress and improvement, or as a means of drawing more closely the ties which unite us to the Mother Country; and, while increasing ' the advantages we derive from that connection, enhancing the value of these colonies to the empire.

I have met with no account of any very recent proceedings towards the establishment of the interoceanic communication between the Atlantic and the Pacific. The last expedition organized to survey the Isthmus of Darien, was in 1854, when the Governments of England, France, the United States, and Granada, assisted in the object of the expedition. The result of that survey shewed that the harbours of Caledonia and Darien, were in every way adapted as the termini of the suggested Canal. It was further ascertained that a range of mountains varying from 900 to 1600 feet in height form the water-parting of the country, at a distance of only five miles from the Atlantic; the distance between the tidal waters on the opposite coast being under thirty miles; but such is the character of this mountain range, that no canal could be there constructed without tunnelling, though a railway might be constructed between ports, not more than thirty-six miles apart, the summit level to be crossed not exceeding nine hundred feet above the sea. Other lines, having the same object, have been suggested and discussed, but the present unsettled political condition of the territories through or near to which any such communication could be established, seems to postpone indefinitely any practical attempt to realize the design.

In passing from this subject it will not be altogether inappropriate to refer to a matter which has been recently discussed, and on which new light has been thrown by Captain Becher, R.N. I allude to the question where Columbus made his first landing on this side the Atlantic. Navarette names Turks Island as the one which the natives called Guanabani, and on which the discoverer conferred the name of San Salvador. Washington Irving on the other hand decides in favour of Cat Island, situated fully 300 miles distant from Turks Island, and which, on every map that I have seen, is marked as the San Salvador of Columbus. Meenoz, who was the Spanish Cosmographer-in-chief for the department of the Indies, in a history of America, of which he lived to publish only the first volume, points out Watling's Island about fifty miles easterly of Cat Island, as the first landfall, and this view Captain Becher supports and confirms. Turning to matters of closer local interest I should make a more extended reference to the Geological Map of Canada, prepared by Sir William Logan, but for the circumstance that during the past year it was produced before this Institute, when Sir William favored the members present with some instructive and highly gratifying observations upon it and upon the geological structure of the Province. We then expressed what I am sure we continue to feel, our full appreciation of the valuable services he has rendered in conducting the Survey still in progress, as well as our pleasure to find that his high merit has been recognized and fitly acknowledged, as well by our Sovereign and the French Emperor, as by some of those Societies in England whose members are peculiarly well qualified to judge of the skill and value of his operations.

There is one more subject of at least equal interest, and of no less importance than any on which I have touched, to which I entreat your brief attention. I allude to education, which may be viewed both in reference to the objects of the Canadian Institute, and also in its more extended relation to the advancement and wellbeing of the Province. As to the former, the observations recently made by Professor Daubeny, so thoroughly, and in such appropriate language, convey what I wish to say, that I gladly avail myself of them. "It begins, indeed, to be generally felt, that amongst the "faculties of mind, upon the development of which in youth, success " in after-life mainly depends: there are some which are best im-" proved through the cultivation of the physical sciences, and that "the rudiments of those sciences are most easily acquired at an "early period of life. That power of minute observation, those " habits of method and arrangement, that aptitude for patient and " laborious enquiry, that tact and sagacity in deducing inferences " from evidence short of demonstration, which the natural sciences " more particularly promote, are the fruits of early education, and " acquired with difficulty at a later period. It is during childhood " also, that the memory is most fresh and retentive, and that the " nomenclature of the sciences, which from its crabbedness and tech-" nicality often repels us at a more advanced age, is acquired almost " without an effort."

It is gratifying to us to know that, so far as is compatible with a system of Common School teaching, elementary instruction in the physical sciences is receiving proper attention; and we may point with pride and pleasure to the conspicuous attainments and ability of many of those who, as Professors in the various branches of literature and science are employed in University education in this Province. We need not go beyond our own ranks to find several who are justly esteemed as authorities in the departments to which their attention is devoted. But in the schools in which preparation is made for a course of University study, it appears to me there is room for improvement in this particular, and I am sure you will concur with me in expressing a hope, that whatever may be found wanting in this important practical department of education may be speedily supplied.

The other branch of the question is of still more serious consequence. We yet, happily, have the opportunity of endeavouring to anticipate and to prevent evils which older communities are striving to mitigate and to cure. The increase of offences committed by the young, forces itself on the attention of Statesmen as well as of Philanthropists. Lord Stanley, not very long ago remarked, in reference to it: "The only means for diminishing crime consists in the detec-"tion and training of criminal children to habits of honest industry:" a sad but pregnant admission, not only of the absence of right education, but of a training in the paths of vice and crime. Our young country has not yet sunk to that stage of demoralization; we may yet, I trust, look with hope and confidence to the prevention of guilt, by training children before they have become initiated in vicious pursuits; and this is the object attainable, as appears to me, through our Common School system. If it requires any changeany new powers to make it thoroughly efficient in that respect, such change should not be delayed, such powers should not, and I believe, could not be long withheld ! No man who seriously reflects on the subject will pay grudgingly the amount he may be taxed to render our Schools accessible to those whose parents or guardians are unable or even unwilling to pay for their education. Every farthing thus expended, will save pounds of the cost attending the detection and punishment of crime. But many will think the taxation neither wise nor just if they see free schools with a comparatively slender attendance, while the streets are filled with idle and vagrant children. ignorant, uneducated, if not already vicious, in danger of falling before the first temptation. It is the office of the Legislature to consider and determine what amount of interference with the rights of parents who neglect this duty to their children should be sanctioned-to what extent and in what manner a needful compulsion should be brought to bear both upon parents and children. It may not be a problem of easy solution, but, I think, it is one that must

be solved. In alluding to this subject here, I trust I have not overstepped the limits, within which, in this place, I ought to confine my remarks, but it is of such paramount importance that scarcely any effort to attract attention to it can be condemned as either illtimed or misplaced.

But it is time that I bring these desultory observations to a close. More than thirty-six years have passed since I first knew Western Canada. An eye-witness of most of the leading events that have happened in her history during that period, an actor in some of them—I cannot compare what is, with what was, without feelings of mixed wonder and rejoicing. The wilderness has given place to fields of standing corn; towns have sprung up where the first blows of the settler's axe had not yet awakened the echoes of the forest; the locomotive dashes on with fiery speed where the early pioneer explored his dubious way by the Indian path; the vessel launched on the waters of Lake Michigan finds her moorings in the River Mersey! I might compare the Province as it was then, to the bark canoe floating on the waters of a river—as it is now, to a gallant ship entering upon the billows of the broad ocean. At first:

> " Through pleasant banks the quiet stream Went winding pleasantly; By fragrant fir groves now it past, And now thro' alder shores ; Through green and fertile meadows now, It silently ran by ! The flag flower blossomed on its side, The willow tresses waved, The flowing current furrowed round The water-lily's floating leaf, The fly of green and gauzy wing Fell sporting down its course. And grateful to the voyager The freshness that it breathed, And soothing to his ear It's murmur round the prow !" \* \* \* \* " But many a silent spring meanwhile, And many a rivulet and rill, Had swollen the growing stream. And when the southern sun began To wind the downward way of Heaven, It ran, a river deep and wide,

A broader and a broader stream.

\* \* \*

"The sun goes down, the Crescent moon Is brightening in the firmament, And what is yonder roar? That sinking now, and swelling now, Still louder, louder grows. \* \* \* \* \* "The moon is bright above,

And the great Ocean opens on their way."

May we not well hope that, under the protection of Divine Providence, the future progress of the Province will be even more prosperous than its past has been. Her children enjoy advantages unsurpassed in the history of any country; a soil whose abundant fertility readily yields to the husbandman the most valuable agricultural products; a climate which, notwithstanding its extremes, brings all those products to full maturity; a system of education, adapted in its elementary portion to the wants of the poorest of the community, and rising to the highest requirements of intellectual culture and scientific attainments; a body of law, devised by the wisdom of past ages, and improved by the experience of successive generations; a constitution, which confers the privilege and imposes the obligation of working out the problem of self-government under the guardianship of the Mighty Empire of which we form part; and above all these: for their guiding star, Christianity, which confers, and be it reverently acknowledged, alone confers the power to satisfy the profoundest longings of the human heart, and to lead all who follow its guidance, to the promised haven of eternal peace.

# NOTE ON THE COMPOSITION OF PARALLEL ROTATIONS.

BY J. B. CHERRIMAN, M. A., CANTAB: PROFESSOR OF NATURAL PHILOSOPHY, UNIVERSITY COLLEGE, TORONTO.

Poinsot, in his famous *Memoire sur la Rotation des Corps*, has pointed out the fundamental connection between the forms to which a system of Forces acting on a rigid body can be reduced, and those by which the motion of a free rigid body at any instant can be exhibited. It is the object of the present note to trace this analogy in a particular case, which has not, so far as I am aware, yet been noticed.

Any system of Forces acting on a rigid body can be reduced to a

single Resultant Force, acting at some assigned point as origin, and to a single resultant couple; the former of these remaining invariable, both in magnitude and direction, whatever origin be assumed while the latter varies in both respects for different origins, remaining constant, however, for origins situated along the direction of the Resultant Force.

Adopting the usual notation by taking as the type of the Forces the rectangular components X, Y, Z of the force acting at the point (x, y, z), we have as resultants at the origin of co-ordinates the single Force whose rectangular components are  $\Sigma(X)$ ,  $\Sigma(Y)$ ,  $\Sigma(Z)$ ; and the single couple whose momental components round the same axes are

$$\mathbf{L} = \Sigma (\mathbf{Z}y - \mathbf{Y}z), \ \mathbf{M} = \Sigma (\mathbf{X}z - \mathbf{Z}x), \ \mathbf{N} = \Sigma (\mathbf{Y}x - \mathbf{X}y).$$

If we now seek the resultants corresponding to an origin whose co-ordinates are (x', y', z'), we find the same Resultant Force, and a new resultant couple (L', M', N'), where

| $\mathbf{L}'$ |   | $\mathbf{L}$ | + | $\Sigma(\mathrm{Y}).z'$ | <br>$\Sigma(Z).y'$          |
|---------------|---|--------------|---|-------------------------|-----------------------------|
| M'            | = | M            | + | $\Sigma(\mathbf{Z}).x'$ | <br>$\Sigma(\mathbf{X}).z'$ |
| N'            | = | Ν            | + | $\Sigma(X).y'$          | <br>$\Sigma(\mathbf{Y}).x'$ |

From these equations we have

 $L' \cdot \Sigma(X) + M' \cdot \Sigma(Y) + N' \cdot \Sigma(Z) = L \cdot \Sigma(X) + M \cdot \Sigma(Y) + N \cdot \Sigma(Z)$ 

Hence if the resultant couple be resolved into two whose axes are respectively perpendicular and parallel to the direction of the Resultant Force, the latter remains invariable in magnitude whatever origin be adopted; and hence also the resultant couple will be the least possible when the origin is so assumed that the former vanishes, or, in other words, when the axis of the couple is in the direction of the Force.

If we seek an origin which shall make the resultant couple vanish, or which shall cause the system of Forces to be reduced to a single resultant Force, we must have for the determination of this origin (x', y', z'),

$$\begin{array}{rcl} \mathbf{L}' &= & \mathbf{o}, & \mathbf{M}' &= & \mathbf{o}, & \mathbf{N}' &= & \mathbf{o}, \\ \mathbf{o} &= & \mathbf{L} &+ & \boldsymbol{\Sigma}(\mathbf{Y})z' &- & \boldsymbol{\Sigma}(\mathbf{Z})y' \\ \mathbf{o} &= & \mathbf{M} &+ & \boldsymbol{\Sigma}(\mathbf{Z})x' &- & \boldsymbol{\Sigma}(\mathbf{X})z' \\ \mathbf{o} &= & \mathbf{N} &+ & \boldsymbol{\Sigma}(\mathbf{X})y' &- & \boldsymbol{\Sigma}(\mathbf{Y})x' \end{array} \right\} \dots \dots \dots (1)$$

These equations are inconsistent unless a certain condition hold, which is,

 $o = L \cdot \Sigma(X) + M \cdot \Sigma(Y) + N \cdot \Sigma(Z) \dots (2)$ 

When this condition is satisfied, (provided  $\Sigma(X)$ ,  $\Sigma(Y)$ ,  $\Sigma(Z)$ , do not all vanish,) the equations (1) are equivalent to only two independent equations, and represent a straight line, every point of which is an origin such as required.

In the particular case where the system consists of Forces in parallel directions, taking F as the type of one of these at the point (x, y, z), and l, m, n for the direction-cosines of their common direction, we have

$$\begin{split} \Sigma(\mathbf{X}) &= l \, \Sigma(F); \, \Sigma(\mathbf{Y}) = m \, \Sigma(F); \, \Sigma(\mathbf{Z}) = n \, \Sigma(F); \\ \mathbf{L} &= n \, \Sigma(\mathbf{F}y) - m \, \Sigma(\mathbf{F}z) \\ \mathbf{M} &= l \, \Sigma(\mathbf{F}z) - n \, \Sigma(\mathbf{F}x) \\ \mathbf{N} &= m \, \Sigma(\mathbf{F}x) - l \, \Sigma(\mathbf{F}y) \end{split}$$

The condition (2) is in this case satisfied, and (provided  $\Sigma(F)$  do not vanish) the equations (1) assume the form

$$\frac{x'-\frac{\Sigma(Fx)}{\Sigma(F)}}{l} = \frac{y'-\frac{\Sigma(Fy)}{\Sigma(F)}}{m} = \frac{z'-\frac{\Sigma(Fz)}{\Sigma(F)}}{n}$$

Hence the line of action of the single Resultant passes through the point whose co-ordinates are  $\frac{\Sigma(Fx)}{\Sigma(F)}$ ,  $\frac{\Sigma(Fy)}{\Sigma(F)}$ ,  $\frac{\Sigma(Fz)}{\Sigma(F)}$ ; these are independent of l, m, n, and this point therefore remains the same so long as the forces and their points of application are unaltered, whatever be their direction; for this reason, it is called the *Centre of Parallel Forces*.

In like manner, the motion at any instant of a free rigid body can be reduced to a single rotation about an axis passing through some assigned point as origin, and to a single motion of translation proper to this origin and common to all the points of the body; the former of these remaining invariable both in magnitude and direction, whatever origin be assumed, while the latter varies in both respects for different crigins, remaining constant, however, for origins situated along the axis of Rotation.

Adopting the usual notation by taking  $\omega_x, \omega_y, \omega_z$ , for the components of the rotation round three rectangular axes, and u, v, w for the components of the velocity of translation along the same axes, we have for the velocities u', v', w,' along these axes, of a point (x', y', z')

$$\begin{array}{rcl} u' &=& u &+& \omega_y z' &-& \omega_z y' \\ v' &=& v &+& \omega_z x' &-& \omega_a z' \\ w' &=& w &+& \omega_x y' &-& \omega_y x' \end{array}$$

94

and these give the motion of translation when the point (x', y', z')is assumed for origin From these equations we have

 $u' \omega_x + v' \omega_y + w' \omega_z = u w_x + v w_y + w \omega_z.$ 

Hence, if the velocity of translation be resolved into two, respectively perpendicular to and along the axis of rotation, the latter remains invariable in magnitude whatever origin be adopted; and hence also the velocity of translation will be the least possible when the origin is so assumed that the former vanishes, or, in other words, when the velocity of translation is in the direction of the axis of Rotation.

If we seek an origin which shall make the motion of translation vanish, or which shall make the whole motion reducible to a single rotation, we must have for the determination of this origin (x', y', z').

u' = 0, v' = 0, w' = 0,

or

| 0 | = | ù | <del>. </del> - | $\omega_y z'$ | _ | $\omega_z y'$ | )               |
|---|---|---|-----------------|---------------|---|---------------|-----------------|
| 0 | = | v | +               | $\omega_z x'$ | _ | $\omega_x z'$ | <b>&gt;</b> (1) |
| 0 | — | w | +               | $\omega_x y'$ |   | $\omega_y x'$ | 5               |

These equations are inconsistent unless a certain condition hold, which is

 $o = u \omega_x + v \omega_y + w \omega_z$  ......(2) When this condition is satisfied (provided  $\omega_x, \omega_y, \omega_z$  do not all vanish), the equations (1) are equivalent to only two independent equations and represent a straight line, every point of which is an origin such as required.

In the particular case where the motion consists of rotations round parallel axes, taking  $\omega$  as the type of one of these about an axis through the point (x, y, z), and l, m, n for the direction-cosines of the common direction of their axes, we have

 $\omega_x = l \Sigma(\omega); \omega_y = m \Sigma(\omega); \omega_z = n \Sigma(\omega).$ 

Also the linear velocity along the axis of x generated in the origin of co-ordinates by one of these rotations  $\omega$  being  $n \omega y - m \omega z$ , we have

$$u = n \Sigma(\omega y) - m \Sigma(\omega z)$$
  

$$v = l - \Sigma(\omega z) - n \Sigma(\omega x)$$
  

$$w = m \Sigma(\omega x) - l \Sigma(\omega y)$$

The condition (2) is in this case satisfied, and (provided  $\Sigma(\omega)$  do. not vanish) the equations (1) assume the form

$$\frac{z' - \frac{\Sigma(\omega z)}{\Sigma(\omega)}}{l} = \frac{y' - \frac{\Sigma(\omega y)}{\Sigma(\omega)}}{m} = \frac{z' - \frac{\Sigma(\omega z)}{\Sigma(\omega)}}{n}$$

95

Hence the axis of the single resultant rotation passes through the point whose co-ordinates are  $\frac{\Sigma(\omega x)}{\Sigma(\omega)}$ ,  $\frac{\Sigma(\omega y)}{\Sigma(\omega)}$ ,  $\frac{\Sigma(\omega z)}{\Sigma(\omega)}$ ; these are independent of *l*, *m*, *n*, and this point therefore remains the same so long as the magnitudes of the rotations, and the points through which their axes are drawn are unaltered, whatever be the common direction of these axes; by analogy this point might be called the *Centre of Parallel Rotations*.

# ON A SMALL CAPILLARY WAVE NOT HITHERTO DESCRIBED.

#### BY JOHN LANGTON, M. A.,

VICE-CHANCELLOR OF THE UNIVERSITY OF TORONTO.

Read before the Canadian Institute, 17th January, 1857.

It is well known that the shape and velocity of waves, and the different circumstances under which they are propagated, have attracted considerable attention amongst men of science, not only from the importance of the subject as connected with the theory of tides, but also from its practical bearing in relation to the resistance of fluids, and the best form for vessels which are destined to move in them. An elaborate report upon waves was prepared by J. Scott Russell, for the British Association, in 1844, the experiments detailed in which have been the origin of some of the greatest improvements of the present day in ship-building, and have inseparably connected the wave line with the name of Russell. Although this report is principally devoted to the solitary wave of translation, which gave rise to the investigation, it treats at less length of other varieties, and may, I believe, be said to embody all that is known upon the subject from observation. There is nothing, however, amongst the waves there enumerated in any way resembling that which I propose bringing under the notice of the Institute to-night, nor have I elsewhere seen any account of its having been previously observed. Amongst all the different kinds of waves, varying as they do in dimensions from the great tidal wave, which, with an elevation of only a few feet, rests upon a base of hundreds of miles in extent, to the ripple which is raised by a summer's breeze, the wave which I am about to introduce to you is, perhaps, the smallest. It

is, indeed, so minute that it might easily have escaped notice, for under ordinary circumstances it cannot much exceed  $\frac{1}{20}$  of an inch in height, and hardly reaches an inch in amplitude. Such an exceedingly minute object may seem scarcely of sufficient interest to form the subject of a paper to be read before the Institute; and being apparently only a disturbance of the capillary film on the surface, which is subject to very different laws and forces from those which govern the motions of the whole mass of a fluid, it is doubtless of much inferior importance to the waves which Russell experimented upon. But as no fact is so trifling that it may not assist in establishing correct views of the operations of nature, and as the Institute has invited communications from its members, giving an account of original observations upon all phenomena, I venture to call attention to some curious particulars which I have noticed respecting this capillary wave, which differs from all others previously described in being a solitary one.

The wave in question may be observed in three different situations. Wherever a large body of water, with a strong current, meets comparatively still and deep water below, it may always be seen, as a sharply defined line, like a hair upon the surface, winding about amongst the numerous eddies which are formed in such situations, ever varying in its outline, and carried along apparently with the general course of the stream, whilst upon the whole it maintains nearly the same position. It is also generally to be found where there exists any impediment to a current, as a dead tree projecting out into a river, or a boom thrown across the stream. In this case the wave may be observed at a distance of from one to three feet above the obstacle, the distance varying with the force of the current. The third case is the reverse of the former one, where a body, propelled through still water, pushes this small wave before it. It occurs much more rarely under these circumstances, and may more easily elude observation, and since my attention has been attracted to it I have often failed to produce it; but it was in this form that I first got any insight into its nature.

Paddling in a canoe in a sheltered bay, with just sufficient air stirring overhead, without raising a ripple on the water, to cause the canoe, when abandoned to itself, to drift broadside on at the rate of perhaps half a mile an hour, I perceived the wave in advance of the canoe, at a distance of about three feet. If the wind died away, the wave was maintained at a greater distance, and upon one occasion I could distinctly trace it so far as from between eight and nine feet

97

VOL. II.-G

from the canoe, beyond which it became fragmentary, and disappeared. If the speed increased suddenly, the wave disappeared, and the slightest ripple on the surface obliterated it at once. But if the wind freshened very gradually, the wave approached nearer and nearer, becoming more strongly defined and more elevated above the surface, and it could still be seen under the lee of the canoe, and at a distance of eight or nine inches from it, after the breeze had increased so as to make a strong ripple on the water outside. If the speed grew still greater, it became first obscured, and finally destroyed, by waves of an entirely different character,—viz., the ripple caused by the canoe itself,—which it is remarkable did not make their appearance in contact with the canoe, but first broke out on the farther side of the capillary wave.

But my attention was principally attracted to the effect which was produced upon the little particles floating near the surface. The opportunity was a good one for observation, for, being in the vicinity of a marsh, the water was very impure, and a bright sunshine enabled me to see the motes at a considerable distance. Light bodies resting on the water without being wetted, as a feather or thistle down, seemed hardly at all affected, except by a slight motion as the wave passed under them; and larger particles, which reached to a depth of perhaps an eighth of an inch, passed it without any disturbance. But smaller ones, floating close to the surface, were violently agitated as the wave reached them, and though they passed a little beyond it, their apparent motion towards the canoe was retarded and finally stopped, at distances from the wave depending upon their respective sizes, the larger ones penetrating the farthest. The interval between the wave and the canoe became thus soon filled with small objects, very regularly sorted according to their sizes, the larger, however, being proportionally much closer together than the smaller ones. If the wind now freshened the wave approached nearer to the canoe, and all the particles were driven in with it, but the smaller ones were much more affected than the larger. If the wind again slackened the wave receded, leaving the particles where they were, and fresh ones were collected in the vacant space, so that, after a few alterations of speed, the regular assortment according to size was soon interfered with, and a miscellaneous scum was pushed on before the canoe, comprising floating matter of all sizes, up to an eighth of an inch or more in depth; for it must be observed, that although objects of that size passed under the wave without disturbance, and penetrated

a long way beyond it without check, their motion was at last arrested before reaching the canoe.

From these facts I was induced to conclude that a body propelled through the water at a low velocity, and with an even regular motion, pushes before it a wedge-shaped film of water, the under surface of which is not a straight line, but a curve of rapidly increasing curvature; that, at very low velocities, this film remains unbroken to a distance of several feet; and that, with increased speed, the distance to which it extends is diminished, whilst its greatest depth remains nearly uniform. There are two things, however, which this supposition will not account for. It will not account for the wave itself: for the film which I have imagined does not appear to extend so far, and under no circumstances did any of the particles, even the smallest, become stationary, till they had passed the wave by about two inches, that interval being always perfectly free from the scum collected. The other circumstance which is left unexplained is, why the feathers and thistle down resting on the water were not also arrested when they came to the film. I do not attempt to account for the difficulty, I only record the facts as I observed them.

I endeavoured to arrive at some conclusion as to the form and size of the wave, but without much success. Its exceeding minuteness, the inconvenient position of the observer in the canoe at a considerable distance from it, and that distance constantly changing with the varying force of the wind, made any accurate measurements almost impossible. I therefore had recourse to the second form, in which I have mentioned that it occurs, where, from the similarity of the circumstances, one would expect to meet with the same facts, and which in many respects afforded greater facilities for observation.

When the water was high in the river in which I made my observations, a great deal of foam came down from the falls above, and at every projecting tree there was a dense collection of froth, with a clear space intervening between it and the wave. Upon clearing away this froth I could observe its gradual re-formation. It was very curious to watch a small patch of foam sailing down with the current. When it approached very close, and in passing the wave, its velocity seemed momentarily increased, but it was then suddenly arrested, whilst there would shoot out from underneath it bits of sawdust, and other matter that had become entangled in it, which would arrange themselves according to their draught of water in the vacant space between the wave and the log, the foam itself remaining

at a distance of about two inches from the wave. Every moment brought down fresh accessions, which gradually pushed on before them that which had already arrived, till the whole space soon became covered as before; but there was always left between the wave and the froth the narrow strip of clear water already mentioned.

Even here it was not easy to ascertain accurately the shape of the wave, in consequence of its constantly shifting with the undulations and irregularities of the current, but I came to the conclusion that it could rarely be more than  $\frac{1}{20}$  of an inch high, and I satisfied myself, from the distortion of objects seen by reflection, that the wave was convex towards the direction of the stream, and concave towards the log, the sensible convexity not extending so much as half an inch beyond the sharply defined cusp, and the concavity not very much more. It became questionable even whether it could be said strictly to be elevated above the surface at all, not only because, if the farther side were convex, it was difficult to conceive how it could regain the level without a corresponding concavity, of which I saw no sign, but also from the consideration of the third form in which the wave may be met with, and which I shall mention presently. I was rather led to conclude that the concave side was depressed below the general level, and that the rise towards the log was very gradual.

I had subsequently an unusually good opportunity of seeing the wave in a very extreme case, where a boom had been stretched across a current running at least six miles an hour. Here it approached sometimes within two inches of the dense mass of rubbish collected on the boom, but always with a perfectly clear space intervening, though much narrower than before. The wave itself was apparently fully a quarter of an inch high, and clearly concave towards the boom and convex beyond; but the question of whether it was the result of an elevation or of a depression of the general surface could not be decided, because the whole mass of water was heaped up against the boom, and the farther slope of the wave was broken into a succession of ripples, very much exceeding the primary wave both in height and amplitude, and differing from it in not being cusped, though otherwise imitating its general shape.

There is one point in which the wave, formed above an impediment in a stream, differs from that seen in advance of a body propelled through still water. At a very low velocity I stated that I had seen it at as great a distance as eight or nine feet from the cance; but in the gentlest stream I do not think I ever saw it as far as four feet from the object which causes it. The reason appears to me to be, that it is easier to maintain the wave already formed than to form it. I do not believe that it would ever be originally produced at such a distance from a moving body; but, being already formed at a higher velocity, its existence may be prolonged under circumstances which of themselves would not have given rise to it.

The third situation in which the wave occurs, as an undulating line amongst the eddies, does not at first sight appear to bear much analogy to those previously mentioned, and I had for many years noticed it without any clue to its origin; but by the light obtained from observations made in the other cases, it was easy to perceive that it was identical in all the three. When there was foam on the river. it was all collected on one side of the little ridge, with a clear strip intervening, and the same checking of the motion of floating particles took place. Although there was no solid body obstructing a stream in this case, there was still water opposing itself to a current, or at least a stream flowing in one direction impeding an eddy setting upon it sideways. On approaching such a wave with a canoe, one may at once perceive how differently the two sides are affected. If you come down upon it broadside on with the stream, the approach of the canoe has no effect upon it, although you advance quickly enough to make a strong ripple, and you can even pass over it and it re-appears undisturbed on the other side. But if you approach in the other direction, you cannot get near it at all. If you advance upon it cautiously, you drive it on before you, and if you press it too hard, ripples begin to shew themselves on its further face, and it breaks up and disappears. In such situations, by careful handling, I have driven a wave so far as to detach a portion of it from the rest, and have carried it on before me for ten or fifteen yards, whilst, after a while, a new wave was formed in the original situation. This may further illustrate the remark which I before made, that it is much easier to maintain one of these waves in existence than to form one, for I never succeeded in producing one in calm water with the irregular motion which accompanies the most careful use of the paddle.

In some cases, where the water boils up from below, you find an irregular circular patch surrounded by one of these waves, and approaching from the outside you may drive it before you till the two sides meet, or by coming upon it end on, you may divide it into two. In this latter case, if it be not very large originally, both the patches will go on rapidly contracting, till they finally run up to a point with a little conical jet; and if the wave be well marked and your motion

## 102 ON A SMALL CAPILLARY WAVE NOT HITHERTO DESCRIBED.

pretty swift, at the moment of disappearance there is a drop of water projected into the air. In such instances, when the circle has become very small, although the motion is too rapid for any precise observation, it is evident to the eye that the included space is elevated above the mean level, which confirms the remark I made when speaking of the shape of the wave.

I believe I have now mentioned all the facts which I have ascertained respecting this apparently insignificant, but in my view very interesting little object, excepting the very different manner in which it is affected by different disturbing causes. As I stated before, if you approach in one direction you may take a cance over it, and it emerges on the other side unimpaired; the irregular currents of an eddy have no effect upon it, except to give it an undulating movement, and I have seen it maintaining its place amongst the standing waves of a rapid when they have been several inches high. I have even raised considerable swells by rocking a cance close to it, and it rides over them without disturbance, but the slightest ripple caused by the wind makes it disappear in a moment; and if spirits of turpentine be dropped on the water a little above it, the whole wave is instantly obliterated, to a distance apparently far beyond that to which the oily film extends.

I regret that I can produce no exact numerical data. I made most of these observations some years ago, in the last days of the fall, and whilst I was making preparations for obtaining more precise results the winter overtook me, and before the opening of the water in the spring other avocations interfered with my plans. The points which it appears desirable to ascertain numerically are, the distances of the wave corresponding to different velocities, and the depths to which the film extends at different intervals, also examined at different velocities. The question also arises, what change, if any, is caused by the depth to which the object generating the wave extends. Whether it be a pier rising from deep water, or a two-inch plank floating on the surface, I think there will be found little or no difference; but one would expect that there must be some limit to the draught of water of an obstacle which would raise a wave, corresponding probably to the greatest depth of the film. I confess that I should like to see the experiment repeated with substances merely resting on the water, without being wetted, for the observations which I made appear to be inexplicable, and I unaccountably omitted to verify them under other circumstances.

As I may probably have no opportunity of continuing my observations myself, I mention these desiderata in case any other member of the Institute should fall in with my little friend and take any interest in the investigation of his history.

#### REVIEW.

Tales of Mystery, and Poems. By Edgar Allan Poe. London: Vizetelly, 1857.

The writings of Edgar Allan Poe have already been appreciated in various forms, and they possess such an individuality of character, and a power of fascination even in their least attractive aspects, that we may be assured they will again and yet again be subjected to re-issue, criticism, censure, and laudation : as intellectual products, ephemeral in their aspect, and yet such as this age at least will not willingly let die. We have purposely selected for our present notice, the volume named at the head of this article, though it is merely a popular selection of a few of Poe's prose writings, issued in a cheap form along with his poems. At another time we may have larger space at our command, and shall then pass under review the more comprehensive literary memorial of this eccentric and wayward child of genius, recently issued from the American press. The publication we refer to is entitled : " The Works of the late Edgar Allan Poe, with a memoir by Rufus Wilmot Griswold; and notices of his genius, by N. P. Willis, and J. R. Lowell." In this latter work four substantial volumes are devoted to the Essays, Poems, and fugitive pieces, and to notices of the biography and genius of Poe,-a writer of whom, if America may not be proud, it is only because the strange moral obliquity of the man, has steeled the hearts of his countrymen against that pride, akin to love, with which they would otherwise have learned to regard the author and the poet. In some striking respects we feel tempted to designate Edgar Allan Poe the Charles Lamb of America -so marked is that strange whimsical individuality of his, that quaint gravity and affectation of seriousness in dealing with a jest. and that sober and deliberate purpose of laughing in his sleeve at the literary lies he successfully palmed upon the most credulous of publics. And yet, assuredly, no two men were every more dissimilar. When, some eleven years after Charles Lamb had been laid beneath the green turf of Edmonton Churchyard, a few survivors of his old circle of friends,-and among the rest his loving biographer, Sir T. N. Talfourd, -met to lay the remains of Mary Lamb along side those of her brother, his biographer thus records the revived memories which the scene awakened: " so dry is the soil of the quiet Churchyard that the excavated earth left perfect walls of stiff clay, and permitted us just to catch a glimpse of the still untarnished edges of the coffin in which all the mortal part of one of the most delightful

persons who ever lived was contained, and on which the remains of her he had loved with love passing the love of woman, were henceforth to rest." How strange the contrast of one whom even we who know him only by his writings cannot help loving, with this author who, like him, expresses such unmistakeable individuality and self-originating characteristics on every page, but only to make us admire with shuddering; as one might gaze on the cold glittering pinnacles of polar ice-cliffs. The poet Lowell has been called in to aid in setting forth the true attributes of his genius, but he had already stamped his just estimate of him in the pungent terseness of a stanza of his "Fable of Critics:"

> "Here comes Poe with his Raven, like Barnaby Rudge, Three-fifths of him genius, and two-fifths sheer fudge; He has written some things far the best of their kind, But some how the heart seems squeezed out by the mind!"

Genius Poe unquestionably had; with eccentricities too, enough to furnish any ordinary half dozen of the irritable race of poets, critics, and editors. But the selfishness of morbid sneering cynicism never took a colder and more repellant aspect; and we look back upon him with a strange sadness as on one of the gifted contributors to the permanent stock of our sources of literary pleasure, whom yet it is all impossible to love. In the prose of Poe, with its odd matter-of-fact anatomising of mystery, there is a singular artificiality of art that seems too much to betray the wires and pulleys of the puppet-master; but few as are his poems, it is difficult to believe the heart so well simulated, if no genial pulsation of human affection and sympathy actually throbbed beneath that cynic heart of his. To these, therefore, the rare and brief out-gushings, as it might seem, of the genuine feeling of "man of woman born," we shall devote such brief space as the demands on our pages admit, in this notice of Edgar Allan Poe; remembering that for him, instead of the hero-worship, which fondly exaggerates the virtues of a favorite author, while "to his faults a little blind," it has been till now his fate to be coarsely anatomised by those who have proved only too willing to expose his frailties, if not to deepen the shadows of his dark life-picture. For this there can beno excuse, for whatever his frailties as a man, no charge can be brought against him of having pandered his genius, or wielded his pen in the cause of vice.

The following brief but touching lyric, is dedicated—we may presume,—to the memory of the same " rare and radiant maiden whom

104

the angels name Lenore," who constitutes the heroine of his more famous "Raven" lyric. But sweet and gracefully touching as are some of the ideas, and musical as are the lines, the "Raven" of Poe's morbid genius flutters ever towards the close, and he winds up this, as well as nearly every other pean, with thoughts born of his own brooding misanthrophy which could well be spared.

## LENORE.

Ah, broken is the golden bowl ! the spirit flown for ever ! Let the bell toll !—a saintly soul floats on the Stygian river; And Guy de Vere, hast *thou* no tear ?—weep now or never more ! See ! on yon drear and rigid bier, low lies thy love, Lenore ! Come ! let the burial rite be read—the funeral song be sung !— An anthem for the queenliest dead that ever died so young— A dirge for her the doubly dead in that she died so young.

"Wretches ! ye loved her for her wealth, and hated for her pride, And when she fell in feeble health, ye blessed her—that she died ! How *shall* the ritual, then, be read ?—the requiem how be sung By you—by yours, the evil eye—by yours, the slanderous tongue That did to death the innocence that died, and died so young ?

Peccavimus ! but rave not thus ! and let a Sabbath song Go up to Godso solemnly the deat may feel no wrong ! The sweet Lenore hath "gone before," with Hope that flew beside, Leaving thee wild for the dear child that should have been thy bride— For her, the fair and *debonnair*, that now so lowly lies, The life upon her yellow hair, but not within her eyes— The life still there upon her hair—the death upon her eyes.

"Avaunt! to-night my heart is light. No dirge will I upraise, But waft the angel on her flight with a pæan of old days ! Let no bell toll ! lest her sweet soul, amid its hallowed mirth, Should catch the note, as it doth float up from the damned earth, To friends above, from fiends below, the indignant ghost is riven— From hell unto a high estate far up within the heaven— From grief and groan, to a golden throne, beside the King of Heaven."

The same strangely morbid bent of thought which mars the beauty of the stanzas here is perhaps even more apparent in his piece called "The Bells," suggested we can scarcely doubt by Moore's "Evening Bells," ringing, unconsciously perhaps, in memory's ear. But the American Poet's theme is, in its starting point at least, a thoroughly native one: the mirthful, heart-enlivening music of the sleigh-bells, which give a music to our long winter that repays in part the coyness of the spring's forest-songsters, and cheeringly contrasts with the melancholy pathos of our summer nightingale, the Whip-poor-will. We say nothing of certain ranal choristers, not unknown as Canadian nightingales! The Sleigh Bell; the Wedding Bell; the Fire Bell; and the Funeral Knell; each in succession has a stanza devoted to it. It is not uncharacteristic, nor without its significance, that the "Sabbath Bell" finds no place in the otherwise comprehensive series. The second and the last of these lyrical peals will suffice to exhibit the poet once more in his real aspect of strange antithesis:

> Hear the mellow wedding bells, Golden bells ! What a world of happiness their harmony fortells! Through the balmy air of night How they ring out their delight! From the molten-golden notes, And all in tune. What a liquid ditty floats To the turtle-dove that listens, while she gloats On the moon ! Oh, from out the sounding cells, What a gush of euphony voluminously swells ! How it swells : How it dwells On the Future ! how it tells Of the rapture that impels To the swinging and the ringing Of the bells, bells, bells, Of the bells, bells, bells, bells, Bells, bells, bells--To the rhyming and the chiming of the bells! \* \* \* Hear the tolling of the bells ! Iron bells! What a world of solemn thought their monody compels! In the silence of the night, How we shiver with affright At the melancholy menace of their tone! For every sound that floats From the rust within their throats Is a groan. And the people-Ah, the people-They that dwell up in the steeple, All alone, And who tolling, tolling, tolling, In that muffled monotone, Feel a glory in so rolling On the human heart a stone-They are neither man nor woman-They are neither brute nor human-

106

They are Ghouls; And their king it is who tolls ; And he rolls, rolls, rolls, Rolls A pæan from the bells! And his merry bosom swells With the pæan of the bells! And he dances, and he yells; Keeping time, time, time, In a sort of Runic rhyme, To the plean of the bells-Of the bells : Keeping time, time, time, In a sort of Runic rhyme, To the throbbing of the bells-Of the bells, bells, bells-To the sobbing of the bells; Keeping time, time, time, As he knells, knells, knells, In a happy Runic rhyme, To the rolling of the bells-Of the bells, bells, bells,--To the tolling of the bells-Of the bells, bells, bells, bells --

Bells, bells, bells-

To the moaning and the groaning of the bells.

Reiteration is carried here to the utmost length short of wearisome satiety ; yet the curious collocation of words must be felt to embody the full ideal of the pealing bells ; and this would be much more apparent could we spare room for the whole piece. The varied power of expression is shown by ringing all the changes of words which each successive bell requires. The merry tinkle of the sleigh-bells ; the mellow voluminous chime of the wedding bells ; the brazen clang of the alarum bells ; and the muffled, throbbing knell of the funeral bells ; each and all of these seem reproduced in imaginary peal, which echoes through the fancy as the eye silently passes over the curious patch-work of rhyme and rythm strung together in artistic semblance of the music they describe.

One example more we must find room for, of a quaint conceit, more than once successfully accomplished by this singular poet, and perhaps most curious as illustrating the same odd fancy for grappling with self-imposed difficulties, which furnishes the strange plots of so many of his tales of mystery. The subject and occasion of the poem is common,—if not common-place—enough; being one of the thousand-and-one verse missives of the Festival of Saint Valentine. Some of the rhymes, here as elsewhere, read strangely to unfamiliar ears, e. g. *Lœda* and *reader*. But such are not without precedent on the American Parnassus. Whittier constantly rhymes such words as *law* and *war*, as in the following couplet:

> "Still shall the glory and the pomp of war Along their train the shouting millions draw."

No one, however, can have read Poe's "Raven" without recognising his complete mastery of the varied cadences of alliteration, resonance, and the ample musical compass of English rhymes; though in the following bagatelle he had other accomplishments in view:

For her this rhyme is penned, whose luminous eyes,

Brightly expressive as the twins of Lœda,

Shall find her own sweet name, that nestling lies Upon the page, enwrapped from every reader.

Search narrowly the lines!—they hold a treasure

Divine—a talisman—an amulet That must be worn at *heart*. Search well the measure— The words—the syllables! Do not forget

The trivialest point, or you may lose your labour !

And yet there is in this no Gordian knot Which one might not undo without a sabre,

If one could merely comprehend the plot. Enwritten upon the leaf where now are peering

Eyes scyntillating soul, there lie *perdus* Three eloquent words oft uttered in the hearing

Of poets, by poets-as the name is a poet's too.

Its letters, although naturally lying

Like the knight Pinto-Mendez Ferdinando-Still form a synonym for Truth.-Cease trying !

You will not read the riddle, though you do the best you can do.

This the reader perchance pronounces no great poctic feat; but he has not yet solved the poet's riddle. In the days of old George Wither, poets were wont to invent for themselves new shackles, and to write rhomboidal dirges, triangular odes, and lozenge-shaped lyrics or canzonets. The acrostic is an old fashion not yet altogether obsolete; and the ordinary restraints of the sonnet, Spenserian stanza, or the ottava rima, still furnish pleasant "poetic pains," as in elder centuries. But the hardest of such poetic labours are trifles compared with that which Poe has here achieved; as will be seen if the reader undertakes its solution according to the following directions. Read the first letter of the first line in connection with the second letter of the second line, the third of the third line, and so on to the end, and the name of the fair object of the poet's pains will be revealed; a name which though far from common is not unfamiliar to Canadian ears, nor without its memorial amongst ourselves. After all, however, it is on his "Raven" that Poe's fame as a poet will rest, and its strange odd mingling of morbid and beautiful fancies with the luscious surfeitings of rhyme, will long attract and repel the reluctantly admiring reader with its curiously fascinating charms.

ENGINEERING AND ARCHITECTURE.

#### INTERESTING EXPERIMENT IN STEAM NAVIGATION.

A trial trip of a steam vessel of an interesting character took place on the river Thames, recently. The Hoyer, a paddle steamer, of nearly 190 tons, and drawing only two feet of water has been constructed to navigate the shallow waters on the west coast of Denmark, between the islands and the mainland. A reference to the map of Denmark will show the peculiar geographical position of this part of the coast. From the river Eider to the Horns reef, a distance of 80 miles, it is bounded by a number of islands, varying in size, and situated from three to ten miles from the shore. They are rich in cattle and grain, and inhabited by a hardy and industrious race, who, from their peculiar position, enjoy but little communication with the mainland; the space between being composed of a long, low flat (partly dry at low water,) and numerous small and intricate channels, difficult and tedious to navigate. The communication hitherto could be made only in small boats, and during bad weather the inhabitants have been unable, for weeks together, to communicate with the coast. The Hoyer (so named after one of the towns) has been constructed to remedy this disadvantage, and in conjunction with the Royal Danish Railway, to place the inhabitants of these hitherto isolated places in daily communication, not only with the coast, but with the whole North of Europe. From her light draught of water, she will pass easily over the flats at tide time, while her size and strength will enable her to navigate the channels, conveying passengers, cattle, and goods with speed and safety. The following are her dimensions :- Length, 120 feet; breath, 181 feet; depth, 74 feet: gross tonnage, 190; horse power, 40; with accommodation for 80 passengers and 100 tons of cargo. On her trial trip, with the wind against her, and with so little hold of the water, she averaged 12 miles an hour, with scarcely any perceptible effort or vibration, and fully realised the expectations of her constructors. She has been built for the Husum and Hoyer Steam Pácket Company, composed of Danish and English proprietors, to ply between those places and the islands, in connection with the Royal Danish Railway, which connects the North Sea with the Baltic. This railway, the result of the skill and enterprise of Sir S. M. Peto and his friends, is now in full operation, and has not only opened a short and expeditious route to the Baltic, but has placed at the disposal of our markets an almost inexhaustible supply of cattle and grain. To the port of Tonning, on the Eider, the North Sea terminus of this railway, a place but little known a few years since, two large steamers, belonging to the North of Europe Steam Navigation Company, ply weekly from London and Hull; whilst on the opposite side, at Flensburg, on the Baltic, a fleet of smaller steamers, belonging to the same company, maintain the communication with Copenhagen, Husum, Aarhuus, Stettin, Dantzic, Konisberg, and St. Petersburg.

# TH E BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE (Concluded.)

CHELTENHAM, 6th August, 1856.

"UNEQUAL SENSIBILITY OF THE FORAMEN CENTRALE TO LIGHT OF DIFFEGENT COLOURS," BY MR. J. C. MAXWELL.

When observing the spectrum formed by looking at a long vertical slit through a simple prism, I noticed an elongated dark spot running up and down in the blue, and following the motion of the eye as it moved up and down the spectrum, but refusing to pass out of the blue into the other colours. It was plain that the spot belonged both to the eye and to the blue part of the spectrum. The result to which I have come is, that the appearance is due to the yellow spot on the retina, commonly called the Foramen Centrale of Soemmering. The most convenient method of observing the spot is by presenting to the eye, in not too rapid succession, blue and yellow glasses, or, still better, allowing blue and yellow papers to revolve slowly before the eye. In this way the spot is seen to fade away in time, and to be renewed every time the yellow comes in to relieve the effect of the blue. By using a Nicol's prism along with this apparatus the brushes of Haidinger are well seen in connexion with the spot, and the fact of the brushes being the spot analyzed by polarized light becomes evident. If we look steadily at an object behind a series of bright bars which move in front of it, we shall see a curious bending of the bars as they come up to the place of the yellow spot. The part which comes over the spot seems to start in advance of the rest of the bar, and this would seem to indicate a greater rapidity of sensation at the yellow spot than in the surrounding retina. But I find the experiment difficult, and I hope for better results from more accurate observers.

"ON AN INSTRUMENT TO ILLUSTRATE POINSOT'S THEORY OF ROTATION," BY MR. J. C. MAXWELL.

In studying the rotation of a solid body according to Poinsôt's method, we have to consider the successive positions of the instantaneous axis of rotation with reference both to directions fixed in space and axes assumed in the moving body. The paths traced out by the pole of this axis on the *invariable plane* and on the *central ellipsoid* form interesting subjects of mathematical investigation. But, when

we attempt to follow with our eye the motion of a rotating body, we find it difficult to determine through what point of the body the instantaneous axis passes at any time,—and to determine its path must be still more difficult. I have endeavoured to render visible the path of the instantaneous axis, and to vary the circumstances of motion, by means of a top of the same kind as that used by Mr. Elliott to illustrate precession. The body of the instrument is a bollow cone of wood, rising from a ring, seven inches in diameter and one inch thick. An iron axis eight inches long, screws into the vertex of the cone. The lower extremity has a point of hard steel, which rests in an agate cup, and forms the support of the instrument. An iron nut, three ounces in weight, is made to screw on the axis, and to be fixed at any point; and in the wooden ring are screwed four bolts, of three ounces, working horizontally, and four bolts, of one ounce, working vertically. On the upper part of the axis is placed a disc of card, on which are drawn four concentric rings. Each ring is divided into four quadrants, which are coloured red, yellow, green and blue. The spaces between the rings are white. When the top is in motion, it is easy to see in which quadrant the instantaneous axis is at any moment, and the distance between it and the axis of the instrument; and we observe :---1st. That the instantaneous axis travels in a closed curve, and returns to its original position in the body. 2nd. That by working the vertical bolts, we can make the axis of the instrument the centre of this closed curve. It will then be one of the principal axes of inertia. 3rd, That by working the nut on the axis, we can make the order of colours either red, yellow, green, blue, or the reverse. When the order of colours is in the some direction as the rotation, it indicates that the axis of the instrument is that of greatest moment of inertia. 4th. That if we screw the two pairs of opposite horizontal bolts to different distances from the axis, the path of the instantaneous pole will no longer be equi-distant from the axis, but will describe an ellipse, whose longer axis is in the direction of the mean axis of the instrument. 5th. That, if we now make one of the two horizontal axes less and the other greater than the vertical axis, the instantaneous pole will separate from the axis of the instrument, and the axis will incline more and more till the spinning can no longer go on, on account of the obliquity. It is easy to see that, by attending to the laws of motion, we may produce any of the above effects at pleasure, and illustrate many different propositions by means of the same instrument.

"ON THE BALAKLAVA TEMPEST, AND THE MODE OF INTERPRETING BAROMETRICAL FLUCTUATION," BY MR. T. DOBSON.

In the month of November, 1854, the passage of a storm over the British islands caused a considerable depression of the barometric column, beginning on the 11th of November and ending on the 19th. During four consecutive days of this period of diminished atmospheric pressure, there occurred in the coal mines of Britain, five fatal explosions, at the following places:—on Nov. 13, at Old Park Colliery, Dudley, Worcestershire; Nov. 14, Cramlington Colliery, Northumberland; Nov. 15, Beunet's Colliery, Bolton, Lancashire, and Birchey Coppice Colliery, Dudley ; Nov. 16, Rosehall Colliery, Coatbridge, N. B. These facts alone render this storm worthy of special attention, independently of the notoriety which it has acquired from its disastrons effects on the allied fleets and armies in the Crimea. The meteorological circumstances which characterized the Balaklava tempest have been determined with unusual care and skill, from a very great number of observations at stations spread over the whole surface of Europe, by M. Liais, of the Imperial

Observatory at Paris. In all probability, many years will elapse before a great storm on land is subjected to an examination so rigorous and complete as that undertaken by M. Liais in the present instance. This storm may, therefore, be adopted as the most satisfactory test that we are likely to have for some time to come of the correctness of the principles of interpretation which I have already applied to barometric fluctuations, in my report on the relation between explosions in coal mines and revolving storms,--principles which flow directly from the nature of cyclones. The cyclonic interpretation in this case would be-First, that the curves indicate the passage of a cyclonic, of which the centre passed to the Southward of England. This is inferred from the gradual increase of the barometric depression from the Orkneys in the north to Teignmouth in the south, and depends on the fact that the height of the mercurial column decreases continuously from the circumference to the centre of the cyclone. This inference is confirmed by the observation that the wind blew from the eastward at all the stations. Second, that the cyclone was progressing to the eastward. This is derived from observing that, at each station, the wind began at S. E. while the mercury was falling, veered to E. when the mercury was lowest, and then to N. E. as the mercury rose. The charts of M. Liais fully establish the truth of the inferences derived above from the contemporaneous barometric curves in Britain. They prove that the Balaklava tempest was a cyclone, moving to the eastward, along a central track which passed to the southward of Britain. It is known that during their transit from the Gulf of Mexico to the western coasts of Europe, across the comparatively uniform surface of the ocean, cyclones preserve an approximately circular form. The excellent charts of M. Liais, at the same time that they exhibit the progress of the storm day by day, from the shores of Britain across the continent of Europe, to the Caucasian mountains and the borders of the Caspian Sea, show also the remarkable modifications produced in the normal condition of the cyclone by mountains and other irregularities of the surface of the land. Thus, for example, a portion of the cyclone is delayed nearly twenty-four hours in passing the Alps. The consequence of this and similar obstructions is, that what was nearly a circular atmospheric wave while crossing the ocean, takes the form of a much elongated and somewhat distorted ellipse on land, enveloping an elliptical central area of maximum barometric depression, which extends, on one chart, from Dantzic in the Baltic to Varna in the Black Sea. Around this central space the wind still blows continuously in the direction peculiar to the cyclones of the northern hemisphere. In the case, therefore, of the Balaklava tempest, whose nature has been determined with much greater exactness than that of any other tempest on land, we have unequivocal testimony that the principles of cyclonology may be safely applied to interpret the fluctuations of the barometer in Great Britain.

#### ON ATMOSPHERIC CURRENTS AT LIVERPOOL.

This was supplementary to Mr. Osler's previous reports, and related to the diurnal laws of the wind when referred to sixteen points of the compass, giving the mean results of above 70,000 observations. It appeared that at Liverpool the various winds have their maximum and minimum velocity at definite and generally different hours. Thus the E.N.E. wind has its maximum about 5 p.m., the E. at 9 p.m., the E.S.E. at midnight, the S.E. at 6 a.m., S.S.E. at 10 a.m., S. at noon, and the corresponding minimums at twelve hours distance from these respectively. The N.N.E. and S.S.W. have each two maximums and minimums in the twenty-four hours. Generally the maximum velocity is about double the minimum.

# AN IMPROVED STEREOSCOPE, BY M. A. CLAUDET.

This is designed to remedy the illusion of curvature shewn by plane surfaces when examined by the refracting or semilenticular stereoscope. This illusion M. Claudet thinks arises from the fact that straight lines, viewed through a prism or semilens, parallel to the base thereof, are bent with a concavity towards the edge of the prism or lens; and both the pictures in the stereoscope being bent in the same manner, their coalescence produces a surface concave to the spectator. To avoid this defect, only the central part of each lens is employed, and the axes of the eyes are to be pointed in nearly parallel directions. In illustration of this theory, M. Claudet mentioned a beautiful optical experiment. If holding a prism in each hand, their refracting edges being vertical and turned towards each other, the window of a room be looked at, at first, two windows are seen with their vertical lines bent in opposite directions : by inclining gradually the optic axes of the eyes, the two images can be made to coincide, and, in the single resulting window, the latent curvature of the vertical lines ceases and is replaced by a curvature from back to front, producing the illusion of a window concave to the spectator.

THE POLYHEDRON OF FORCES, BY MR. J. T. GRAVES.

"If any number of forces act upon a point and be represented in magistude by the areas of the faces of a polyhedron, their directions being normal to these faces, they will keep the point at rest."

This is an extension of the well known principle of the "Polygon of Forces." It can also be applied to the composition of Couples, and Linear and Rotatory velocities after the manner of Poinsot.

### THE LAW OF THE SQUARES-IS IT APPLICABLE OR NOT TO THE TRANSMISSION OF SIGNALS IN SUBMARINE CIRCUITS ?"-BY MR. O. W. WHITEHOUSE.

Before proceeding to the consideration of this subject, the author wished to explain, with reference to his paper read on a previous day, that it was for the purpose of determining the force of either intermitting or alternating currents. whose duration was not sufficient to admit of the needle assuming a position of rest. that he proposed the use of the magneto-electrometer-an instrument rendering available the force of magnetic attraction instead of the deflection of the needleas a means of measuring the amount of current circulating. This force was, he said, until we approach the point of magnetic saturation of the iron, strictly proportioned to the energy of the current under examination. The number of grains thus lifted on the arm of the lever, the author proposes to call the practical "value" of the current for telegraphic purposes. The most striking features of this instrument are-1st. The facility of determining the value of currents which do not admit of being tried by the galvanometer;-2nd. The very great range which this instrument has (viz., from unity up to half a million,) as well as the definiteness and accuracy of the results, even the extremes of the register being strictly comparable with each other ;- 3rd. Unlike the degrees upon the galvanometer, these grains of force are units of real "value" and of practical utility, as was shown by a telegraphic instrument in circuit being worked perfectly by a current of four grains. Referring to the proceedings of this Section last year, at Glasgow, the author quoted Prof. W. Thomson's paper on this subject, where he stated "that a part of the theory communicated by himself to the Royal Society last May, and published in " VOL. II.--H

113

#### BRITISH ASSOCIATION FOR THE

the proceedings, shews that a wire of six times the length of the Varna and Balak. lava wire, if of the same lateral dimensions, would give thirty six times the retardation, and thirty-six times the slowness of action. If the distinctness of utterance and rapidity of action practicable with the Varna and Balaklava as not to be inconvenient, it would be necessary to have a wire of six times the diameter or better, thirty-six wires of the same dimensions, or a larger number of small wires twisted together, under a gutta-percha covering, to give tolerably convenient action by a submarine cable of six times the length." The author then stated, that circumstances had enabled him to make very recently a long series of experiments upon this point, the results of which he proposed to lay before the Section ; adding, that an opportunity still existed for repeating these experiments upon a portion of cable to which he could obtain access, and that he was ready to show them before a committee of this Section in London, if the important nature of the subject should seem to render such a course desirable. Although the subject of submarine telegraphy had many points of the highest importance requiring investigation, and to the consideration of which he had been devoting himself recently, Mr. Whitehouse proposed to confine his remarks on this occasion to the one point indicated in the title, inasmuch as the decision of that one, either favourably or otherwise, would have, on the one hand, the effect of putting a very narrow limit to our progress in telegraphy, or, on the other, of leaving it the most ample scope He drew a distinction between the mere transmission of a current across the Atlantic (the possibility of which he supposed everybody must admit) and the effectual working of a telegraph at a speed sufficient for "commercial success;" and we gathered from his remarks that there were those ready to embark in the undertaking as soon as the possibility of "commercial success" was demonstrated. The author then gave a description of the apparatus employed in his researches, of the manner in which the experiments were conducted, and, lastly, of the results obtained. The wires upon which the experiments were made were copper, of No. 16 gauge, very perfectly insulated with gutta-percha-spun into two cables, containing three wires of equal length (83 miles,) covered with iron wires and coiled in a large tank in full contact with moist earth, but not submerged. The two cables were subsequently jointed together, making a length of 166 miles of cable, containing three wires. In addition to this, in some of the latest experiments, he had also the advantage of another length of cable, giving, with the above, an aggregate of 1,020 miles. The instruments, one of which was exhibited, seemed to be of great delicacy, capable of the utmost nicety of adjustment, and particularly free from sources of error. The records were all made automatically, by electro-chemical decomposition, on chemically prepared paper. The observations of different distances recorded themselves upon the same slip of paper,--thus, 0.83 and 249 miles were imprinted upon one paper, 0.83, 498 miles upon another slip, and 0.249, 498 upon another, and 0.535, 1,020 upon another. Thus, by the juxtaposition of the several simultaneous records on each slip, as well as by the comparison of one slip with another, the author has been enabled to show most convincingly that the law of the squares is not the law which governs the transmission of signals in submarine circuits. Mr. Whitehouse showed next, by reference to published experiments of Faraday's and Wheatstone's (Philosophical Maga. zine, July, 1855,) that the effect of the iron covering with which the cable was surrounded was, electrically speaking, identical with that which would have resulted from submerging the wire, and that the results of the experiments could
not on that point be deemed otherwise than reliable. The author next addressed himself to the objections raised against conclusions drawn from experiments in "Multiple" cables. Faraday had experimented, he said, upon wires laid in close juxtaposition, and with reliable results; but an appeal was made to direct experiment, and the amount of induction from wire to wire was weighed, and proved to be as one to ten thousand, and it was found impossible to vary the amount of retardation by any variation in the arrangement of the wires. Testimony, also, on this point was not wanting. The Director of the Black Sea Telegraph, Lieut. Col. Biddulph, was in England, and present at many of the experiments. He confirmed our author's view, adding, "that there was quite as much induction and embarrassment of instruments in this cable as he had met with in the Black Sea line." The author considers it, therefore, proved "that experiments upon such a cable, fairly and cautiously conducted, may be regarded as real practical tests, and the results obtained as a fair sample of what will ultimately be found to hold good practically in lines laid out in extenso. At the head of each column in the annexed table is stated the number of observations upon which the result given was computed,-every observation being rejected on which there could fall a suspicion of carelessness, inaccuracy, or uncertainty as to the precise conditions; and, on the other hand, every one which was retained being carefully measured to the hundredth part of a second. This table is subject to correction, for variation in the state of the battery employed, just as the barometrical observations are subject to correction for temperature. Of this variation as a source of error I am quite aware, but I am not yet in possession of facts enough to supply me with the exact amount of correction required. I prefer, therefore, to let the results stand without correction.

— Now it needs no long examination of this table to find that we have the retardation following an increasing ratio,—that increase being very little beyond the simple arithmetical ratio. I am quite prepared to admit the possibility of an amount of error having crept into these figures, in spite of my precautions; indeed, I have on that account been anxious to multiply observations in order to obtain most trustworthy results. But I cannot admit the possibility of error having accumulated to such an extent as to entirely overlay and conceal the operation of the law of the squares, if in reality that law had any bearing on the results. Taking 83 miles as our unit of distance, we have a series of 1, 2, 3, 6, and 12. Taking 166 miles as our unit we have then a series of 1, 8, and 6. Taking 249 miles, we have still a series of 1, ,2 and 4, in very long distances. Yet even under these circumstances, and with these facilities, I cannot find a trace of the operation of that law." The author then examined the evidence of the law of the squares, as shown by the value of a current taken in submarine or subterranean wires at different distances from the

generator thereof, which he showed were strongly corroborative of the previous results. He next examined the question of the size of the conducting wire; and he had the opportunity of testing the application of the law, as enunciated by Prof. Thomson last year. The results, far from confirming the law, are strikingly opposed to it. The fact of trebling the size of the conductor augmented the amount of retardation to nearly double that observed in the single wire. The author, however, looked for the experimentum crucis in the limit to the rapidity and distinctness of utterance attainable in the relative distances of 500 and 1,020 miles. 350 and 270 were the actual number of distinct signals recorded in equal times through these two lengths respectively. These figures have no relation to the squares of the distance. "Now, if the law of the squares be held to be good in its application to submarine circuits, and if the deductions as to the necessary size of the wire, based upon that law, can be proved to be valid also, we are driven to the inevitable conclusion that submarine cables of certain length to be successful must be constructed in accordance with these principles. And what does this involve? In the case of the Transatlantic line, whose estimated length will be no less than 2,500 miles, it would necessitate the use, for a single conductor only, of a cable so large and ponderous, as that probably no ship except Mr. Scott Russell's leviathan could carry it, -- so unwieldy in the manufacture, that its perfect insulation would be a matter almost of practical impossibility,-and so expensive, from the amount of materials employed, and the very laborious and critical nature of the processes required in making and laying it out, that the thing would be abandoned as being practically and commercially impossible. If, on the other hand, the law of the squares be proved to be inapplicable to the transmission of signals by submarine wires, whether with reference to the amount of retardation observable in them, the rapidity of utterance to be attained, or the size of conductor required for the purpose, then we may shortly expect to see a cable not much exceeding one ton per mile, containing three, four or five conductors, stretched from shore to shore, and uniting us to our Transatlantic brethren, at an expense of less than one-fourth that of the large one above mentioned, able to carry four or five times the number of messages, and therefore yielding about twenty times as much return in proportion to the outlay. And what, I may be asked, is the general conclusion to be drawn as the result of this investigation of the law of the squares applied to submarine circuits? In all honesty, I am bound to answer, that I believe nature knows no such application of that law; and I can only regard it as a fiction of the schools, a forced and violent adaptation of a principle in Physics, good and true under other circumstances, but misapplied here."

In reply to this, Prof. W. Thomson writes to the *Atheneum*, that he believes Mr. Whitehouse's results are reconcileable with his theory, because he is confident that the theory is true, though he is not confident that he sees the true way of reconcilement; and, in the mean time, he believes that a more "matter of fact" proof must be afforded of the possibility of attaining sufficient capacity of communication through a cable 1,000 miles long, than Mr. Whitehouse's experiments supply. Mr. Whitehouse, in answer, says, that this "matter of fact" proof has been given—in short—"we have recently telegraphed at a commercially satisfactory speed through an unbroken subterranean circuit of 2,000 miles." Prof. Thomson, (*Atheneum*, Nov. 1,) now enters into an elaborate discussion, in which he appears to concede the question so far as the practical working of the telegraph is concerned with the "law of squares:" he shews that in results calculated from the theory, the deviations, from the law of squares, occur to as great an extent as in Mr. Whitehouse's actual experiments; these deviations, depending on the precise nature "of the electrical operations performed at one end of the wire, and of the test of electrical effect afforded by the receiving instrument at the other hand."

ON THE MANUFACTURE OF IRON AND STEEL WITHOUT FUEL, BY MR. W. BESSAMER.

Mr. Bessamer asserted that crude iron contains about 10 per cent. of carbon; that carbon cannot exist at white heat in the presence of oxygen, without uniting therewith and producing combustion, that such combustion would proceed with a rapidity dependent on the amount of surface of carbon exposed; lastly, that the temperature which the metal would acquire would be also dependent on the rapidity with which the oxygen and carbon were made to combine, and consequently that it was only necessary to bring the oxygen and carbon together in such a manner that a vast surface should be exposed to their mutual action in order to produce a temperature hitherto unattainable in our largest furnaces. With a view of testing practically this theory, he had constructed a cylindrical vessel of three feet in eight, somewhat like an ordinary cupola furnace, the interior of which was lined with fire-bricks; and about two inches from the bottom of it inserted five tuyere pipes, the nozzles of which were framed of well burnt fire-clay, the orifice of each tuyere pipe being about three-eighths of an inch in diameter. These were so put into the brick lining (from the outer side) as to admit of their removal and renewal in a few minutes when they were worn out. At one side of the vessel, about half way up from the bottom, there was a hole made for running in the crude metal, and on the opposite side there was a tap-hole stopped with loam, by means of which the iron was run out at the end of the process. The vessel should be placed so near to the discharge-hole of the blast furnace as to allow the iron to flow along a gutter into it. A small blast cylinder would be required, capable of compressing air to about 8 lb. or 10 lb. to the square inch. A communication having been made between it and the tuyeres before named, the converting vessel would be in a condition to commence work. It would, however, on the occasion of its being first used after re-lining with fire-bricks, be necessary to make a fire in the interior with a few baskets of coke, so as to dry the brickwork and heat up the vessel for the first operation, after which the fire would have to be all carefully raked out at the tapping-hole, which would again be made good with loam. The vessel would then be in readiness to commence work, and might be so continued without any use of fuel, until the brick lining in the course of time became worn away and a new lining was required. The tuyeres are situated nearly close to the bottom of the vessel; the fluid metal will therefore rise some eighteen inches or two feet above them. It is necessary, in order to prevent the metal from entering the tuyere-holes, to turn on the blast before allowing the fluid crude iron to run into the vessel from the blast furnace. This having been done, and the fluid iron run in, a rapid boiling up of the metal will be heard going on within the vessel, the metal being tossed violently about, and dashed from side to side, shaking the vessel by the force with which it moves from the throat of the converting vessel. Flame will then immediately issue, accompanied by a few bright sparks. This state of things will continue for about 15 or 20 minutes, during which time the oxygen in the atmospheric air combines with the carbon contained in the iron, producing carbonic acid gas, and at the same time evolving a powerful heat. Now, as this heat is generated in the interior of. and is diffused in innumerable fiery bubbles through the whole fluid mass, the metal absorbs the greater part of it, and its temperature becomes immensely increased ;

and by the expiration of the 15 or 20 minutes before named, that part of the carbon which appears mechanically mixed and diffused through the crude iron has been entirely consumed. The temperature, however, is so high that the chemi-, cally-combined carbon now begins to separate from the metal, as is at once indicated by an immense increase in the volume of flame rushing out of the throat of the vessel. The metal in the vessel now rises several inches above its natural level, and a light frothy slag makes its appearance, and is thrown out in large foam-like masses. This violent eruption of cinder generally lasts five or six minutes, when all further appearance of it ceases—a steady and powerful flame replacing the shower of sparks and einder which always accompanies the boil. The rapid union of carbon and oxygen which thus takes place adds still further to the temperature of the metal, while the diminished quantity of carbon present allows a portion of the oxygen to combine with the iron, which undergoes combustion, and is converted into an oxide. At the excessive temperature that the metal has now acquired, the oxide, as soon as formed, undergoes fusion, and forms a powerful solvent of those earthy bases that are associated with the iron. The violent ebullition, which is going on mixes most intimately with scoriæ and metal, every part of which is thus brought into contact with the fluid, which will thus wash and cleanse the metal most thoroughly from the silica and other earthy bases which are combined with the crude iron, while the sulphur and other volatile matters which cling so tenaciously to iron at ordinary temperatures are drawn off, the sulphur combining with the oxygen, and forming sulphurous acid gas. The loss in weight of crude iron during its conversion into an ingot of malleable iron, was found, on a mean of four experiments, to be 123 per cent., to which will have to be added the loss of metal in the finishing rolls. This will make the entire loss probably not less than 18 per cent, instead of about 28 per cent., which is the loss on the present system. A large portion of this metal is, however, recoverable, by treating with carbonaceous gases the rich oxides thrown out of the furnace during the boil. These slags are found to contain innumerable small grains of metallic iron, which are mechanically held in suspension in the slags, and may be easily recovered, by opening the tap hole of the converting vessel, and allowing the fluid malleable iron to flow into the iron ingot moulds placed there to receive it. The masses of iron thus formed will be perfectly free from any admixture of cinder, oxide, or other extraneous matters, and will be far more pure and in a sounder state of manufacture than a pile formed of ordinary puddle bars. And thus it will be seen that by a single process, requiring no manipulation or particular skill, and with only one workman, from three to five tons of crude iron passes into the condition of several piles of malleable iron in from thirty to thirty-five minutes, with the expenditure of about one-third part the blast now used in a fiery furnace with an equal charge of iron, and with the consumption of no other fuel than is contained in the crude iron. To persons conversant with the manufacture of iron (said Mr. Bessamer), it will be at once apparent that the ingots of malleable metal which I have described will have no hard or steely parts, such as are found in puddled iron, requiring a great amount of rolling to bland them with the general mass; nor will such ingots require an excess of rolling to expel cinder from the interior of the mass, since none can exist in the ingot, which is pure and perfectly homogeneous throughout, and hence requires only as much rolling as is necessary for the developement of fibre; it therefore follows that, instead of forming a merchant bar or rail by the union of a number of separate pieces welded together, it

will be far more simple and less expensive to make several bars or rails from a single ingot. Doubtless this would have been done long ago, had not the whole process been limited by the size of the ball which the puddler could make. I wish to call the attention of the Meeting to some of the peculiarities which distinguish cast steel from all other forms of iron-namely, the perfect homogeneous character of the metal, the entire absence of sand cracks or flaws, and its great cohesive force and elasticity, as compared with the blister steel from which it is madequalities which it derives solely from its fusion and formation into ingots, all of which properties malleable iron acquires in a like manner by its fusion and formation into ingots in the new process; nor must it be forgotten that no amount of rolling will give to blister steel (although formed of rolled bars) the same homogeneous character that cast steel acquires by a mere extension of the ingot to some ten or twelve times its original length. One of the most important facts connected with the new system of manufacturing malleable iron is, that all the iron so produced will be of that quality known as charcoal iron; not that any charcoal is used in its manufacture, but because the whole of the processes following the smelting of it are conducted entirely without contact with, or the use of any mineral fuel; the iron resulting therefrom will in consequence be perfectly free from those injurious properties which that description of fuel never fails to impart to iron that is brought under its influence. At the same time this system of manufacturing malleable iron offers extraordinary facility for making large shafts, cranks, and other heavy masses. It will be obvious that any weight of metal that can be founded in ordinary cast iron by the means at present at our disposal may also be founded in molten malleable iron, to be wrought into the forms and shapes required, provided that we increase the size and power of our machinery to the extent necessary to deal with such large masses of metal. A few minutes' reflection will show the great anomaly presented by the scale on which the consecutive processes of iron making are at present carried on. The little furnaces originally used for smelting ore have been from time to time increased in size until they have assumed colossal proportions, and are made to operate on two or three hundred tons of materials at a time, giving out ten tons of fluid metal at a single run The manufacturer has thus gone on increasing the size of his smelting furnaces, and adapting to their use the blast apparatus of the requisite proportions, and has by this means lessened the cost of production in every way. His large furnaces require a great deal less labor to produce a given weight of iron than would have been required to produce it with a dozen furnaces; and in like manner he diminishes his cost of fuel, blast and repairs, while he insures a uniformity in the result that never could have been arrived at by the use of a multiplicity of small furnaces. While the manufacturer has shown himself fully alive to these advantages, he has still been under the necessity of leaving the succeeding operations to be carried out on a scale wholly at variance with the principles he has found so advantageous in the smelting department. It is true that hitherto no better method was known than the puddling process, in which from 400 lb. to 500 lb weight of iron is all that can be operated upon at a time; and even this small quantity is divided into homeopathic doses of some 70 lb. or 80 lb., each of which is moulded and fashioned by human labor, and carefully watched and tended in the furnace, and removed therefrom one at a time, to be carefully manipulated and squeezed into form. When we consider the vast extent of the manufacture, and the gigantic scale on which the early stages of the process is conducted, it is astonishing that no effort

should have been made to raise the after-processes somewhat nearer to a level commensurate with the preceding ones, and thus rescue the trade from the trammels which have so long surrounded it. Before concluding these remarks, I beg to call your attention to an important fact connected with the new process, which affords peculiar facilities for the manufacture of cast steel. At that stage of the process, immediately following the boil, the whole of the crude iron has passed into the condition of cast steel of ordinary quality. By the continuation of the process the steel so produced gradually loses its small remaining portion of earbon, and passes successively from hard to soft steel, and from soft steel to steely iron, and eventually to very soft iron; hence, at a certain period of the process any quality of metal may be obtained. There is one in particular, which, by way of distinction, I call semi-steel, being in hardness about midway between ordinary cast steel and soft malleable iron. This metal possesses the advantage of much greater tensile strength than soft iron. It is also more elastic, and does not readily take a permanent set, while it is much harder and is not worn or indented so easily as soft iron. At the same time it is not so brittle or hard to work as ordinary cast steel. These qualities render it eminently well adapted to purposes where lightness and strength are specially required, or where there is much wear, as in the case of railway cars, which from their softness of texture soon become destroyed. The cost of semi-steel will be a fraction less than iron, because the loss of metal that takes place by oxidation in the converting vessel is about two and a half per cent. less than it is with iron; but as it is a little more difficult to roll, its cost per ton may be fairly considered to be the same as iron. But as its tensible strength is some thirty or forty per cent. greater than bar iron, it follows that for most purposes a much less weight of metal may be used; so that taken in that way the semi-steel will form a much cheaper metal than any we are at present acquainted with. The facts which I have brought before the Meeting are not mere laboratory experiments, but the result of working on a scale nearly twice as great as is pursued in our largest ironworks-the experimental apparatus doing 7 cwt. in thirty minutes while the ordinary puddling furnace makes only  $4\frac{1}{2}$  cwt. in two hours, which is made into six separate balls, while the ingots or blooms are smooth, even prisms, ten inches square by thirty inches in length, weighing about equal to ten ordinary puddle balls.

RESEARCHES IN THE CRIMEAN BOSPHORUS, AND ON THE SITE OF THE ANCIENT GREEK CITY OF PANTICAPCEUM (KERTCH), BY DR. D. MACPHERSON.

The present town of Kertch is built close to the site where 500 years n. c. the Milesians founded a colony. About fifty years before Christ, this colony became subject to Rome, or rather a Satrap of the Roman Empire, from the circumstance of the Bosphorian kings, who were also rulers of Pontus, having been subdued by this people in Asia. In the year 375 of our era, the colony was utterly annihilated by the Huns. Barbarous hordes succeeded one upon another thereafter until A. D. 1280, when the Genoese became possessors of the soil, and held it until expelled by the Turks in 1473; they being in their turn expelled in 1771 by the Ruesians. The characteristic features around Kertch are the immense tumuli, or artificial mounds that abound in this locality, more especially within the second vallum. These sepulchres of the ancient world are found in many places. We have them in the form of barrows in England, and cairns in Scotland. Calculated as they are for almost endless duration, they present the simplest and sublimest monument that

could have been raised over the dead. The size and grandeur of the tumuli found in this locality excite astonishing ideas of the wealth and power of the people by whom they were erected, for the labour must have been prodigious and the expen-The highest specimens of Hellenic art have been discovered in diture enormous. these tumuli-such as sculpture, metal, alabaster and Etruscan vases, glass vessels, remarkable for their lightness, carved ivory, coins, peculiarly pleasing on account of their sharpness and finish, and trinkets, executed with a skill that would vie with that of our best workmen. All originals were forwarded to the Hermitage, at St. Petersburgh, duplicates being preserved in the Museum at Kertch, and these might have been with ease secured to England on the investment of the place by the Allies; but with the exception of some bas-reliefs, which, in connexion with other two officers, I transmitted to the British Museum, the whole of these rare treasures were barbarously made away with. The local tradition is, that these tunuli were raised over the remains, and to perpetuate the memory, of the kings or rulers who held sway over the colonists, and that the earth was heaped upon them annually on the anniversary of the decease of the prince, and for a period of years corresponding to the rank or respect in which its tenant was held, or had reigned; and to this day successive layers of earth, which were laid on in each succeeding year, can be traced in their coating of sea-shell or charcoal having been first put down. I have counted as many as 30 layers in a scarp made in one of those mounds, about two-thirds from its base. They are to be seen of all sizes, varying from 10 to 300 feet in circumference, and in height from 5 to 150 feet, and are usually composed of surface soil and rubble masonry. Herodotus' reference to these sepulchres is the earliest account which history has recorded of this mode of burial; and I would particularly draw your attention to his description of the mode adopted by the Scythians to perpetuate the memory of their deceased princes, for you will hereafter see that one of my excavations corresponded exactly with the description given by him. "The tombs of the Scythian kings," he states, "are seen in the land Gberri, at the extreme point to which the Borysthenes is navigable. Here, in the event of a king's decease, after embalming the body, they convey it to some neighbouring Scythian nation. The people receive the royal corpse, and convey it to another province of his dominions, and when they have paraded it through all the provinces, they dig a deep square fosse, and place the body in the grave on a bed of grass. In the vacant space around the body in the fosse they now lay one of the king's concubines, whom they strangle for the purpose, his cup-bearer, his cook, his groom, his page, his messenger, fifty of his slaves, some horses, and samples of all his things. Having so done, all fall to work, throwing up an immeuse mound, striving and vying with each other who shall do the most. The Greeks, who always respected the religion of the countries they had subjugated, and who, in process of time, imbibed, to a certain extent, their customs and observances, appear to have adopt. ed this Scythian mode of burial. Instead, however, of placing their magistrates or rulers in a "deep square fosse" dug in the earth, they built tombs, and over these raised the conical hill. But I examined several without meeting with any success. All, or nearly all, of these tumuli have been already explored. Not far from Mons Mithridates I came upon a portion of an aqueduct which probably conveyed water to the Acropolis. It was formed of concave tiles; one of these, with a Greek name thereon, I have brought with me. On one occasion I arrived at the place where five stone tombs were found adjoining, neither of which contained any relic, but in a spot contiguous a large ornamented earthenware jug and five glass

cups, one within the other, were discovered. It was not unusual thus to find the remains in one spot and the ornaments in another. On removing the earth off the sides of a rock, the apex of which was only perceptible on the summit, I struck upon a recess, three sides of a square chiselled out of a rock 16 feet in length and 8 in depth. Following this, I reached a stone seat; hewn out on each side of this seat small recesses had been made, apparently for the purpose of receiving lamps. After descending 12 feet I came to human remains, and for five days the workmen turned nothing out of this pit but human bones. How far these would have descended I know not, for I ceased my explorations here, feeling satisfied, from the appearance of the bones, that they must have been placed there at the same period-the result, most probably, of some great engagement, for many of the skulls and long bones presented fractures and injuries. The marks on the rock would indicate that sacrificial meetings, possibly commemorative of the event, were held here. Replacing these remains, I preceded to a point indicated as the tombs of the diminutive or pigmy race, but discovered nothing that would indicate a peculiar class of people. Beneath an extensive sloping artificial tumulus, running at right angles with the the ridge extending northwards from Mons Mithridates, I came upon a mass of rubble masonry, beyond which was a door leading to an arched chamber, built under the side of the mound. This led me to a larger chamber, which was also arched. The walls of the larger chamber were marked off in squares, with here and there flowers, birds, and grotesque figures. Over the entrance into this chamber were painted two figures of griffins rampant, two horsemen, a person in authority and his attendant-the latter carrying in his hand a long spear-being rudely sketched on one of the inner walls. There were no remains of any sort in this tomb or temple. A recess in the walls on two sides resembled doors blocked up. On removing the masonry to the right the skeleton of a horse was found. To the left a human skeleton lay across the door. Tunnelling on each side, the work was carried on beneath the descents of former explorations from above. On the right-hand side the tunnel extended ten yards, but nothing of interest was met with. On the left, descending as the tunnel was formed, arriving occasionally at objects possessing much interest, I came upon a layer of natural slate rock, the sides and roof of the tunnel being composed of artificial soil, charcoal, animal remains, and, as usual, heaps of broken pottery. Thirty feet from the entrance, the rock suddenly disappeared to the front and left, the mark of the chisel being perceptible on the divided portion. Tunnelling in the rock, we again reached 12 feet from the spot where it had disappeared, loosesand occupying the intervening space, into which the exploring rod, six feet long, dropped without any effort. I worked down into this shaft 12 feet. But the left side of the shaft, which was composed of the same loose sand as far as the steel rod could reach, was continually falling in. Moreover, the labour carried on by candlelight of raising the earth in baskets, and conveying it in wheelbarrows to the outside through the building was becoming very arduous, and I was compelled to abandon the work. At this period no relics or remains of any sort were discovered, and the steel rod sunk into the loose sand as if it had been so much flour. I felt satisfied that this shaft led to rich treasures below, but regard for the safety of my workmen prevented my proceeding deeper. The tunnel was carried on a few feet further, and the earth allowed to drop into the shaft. I now sought out other ground, and selected a place removed about 100 yards from that I had just left. Descending some ten feet, I struck upon a tomb cut out of the solid rock. Not far from this my attention was attracted to an excavation in the rock, somewhat similar

to, but on a much smaller scale, than that large descent which I had just abandoned. Clearing the surface, I found that the rock was hewn out 3 feet in width and 12 in length, the intervening space being filled with sand, similar in all respects to the other into which the steel rod sunk with ease. Fifteen feet of this sand being removed, I came upon the skeleton of a horse. A few feet further on, an upright flag, four feet high, and the breadth of the shaft, was placed over the entrance of a tomb cut out of the calcareous clay. The opening faced the east by an arched door, 24 inches wide and 32 high. The tomb was of a semi-circular form, arched, 10 feet by 12 in diameter, and 8 feet high in the centre. Above the doorway a lintel-stone was placed, on which the slab which closed it rested. The cavity was cut out of the natural calcareous clay, which was firm and consistent, the form and <sup>shape</sup> of the instrument by which it had been removed being very distinct. The candle burnt brightly on entering. The floor was covered with beautiful pebbles and shells, such as are now found on the shores of the Sea of Azov. A niche was cut out of the walls on three sides, in which lay the dust of what once was human. It was a sight replete with interest to survey this chamber-to examine each article as it had been originally placed more than 2,000 years ago-to contemplate its use, and to behold the effect of 20 centuries upon us proud mortals. There lay the dust of the human frame, possessing still the form of man. The bones had also crumbled into dust; the space once occupied by the head did not exceed the size of the palm of the hand, but in the undisturbed dust, the position of the features could still be traced. The mode in which the garments enveloped the body, and the knots and fastenings by which these were bound, being also distinct. On each niche a body had been placed, and the coffins, crumbled into powder, had fallen in. At the head were glass bottles-one of these contained a little wine. A cup and a lacrymatory of the same material and a lamp were placed in a small niche above. A coin and a few enamelled beads were in the left hand, and in the right a number of walnuts-the wine and nuts being doubtless placed there to cheer and support the soul in its passage to Paradise. Some fibulæ and common ornaments, valuable only on account of their antiquity, were also found. Continuing my researches in the same locality, I came upon other similar shafts, at the end of which were the bones of a horse, and then the large flagstone closed the mouth of tombs similar to the last. I now resolved to made another attempt to explore the great shaft: the only mode of effecting this being to remove entirely that portion of the hill above it, I brought all my labourers to the spot, although the few days that remained of our sojourn in Kertch would hardly enable me, I feared, to complete the work. Placing my men in two gangs, each were made to work half an-hour without ceasing. On the third day we struck on two large amphoræ, containing each the skeleton of a child between four and six years of age. Underneath these were the tombs of two adults, and then came the skeleton of a horse. There was now every indication that a great feast or sacrifice had been held, for a few feet further on we came upon immense heaps of broken amphora, fragments of wine jars, the inside of which were still encrusted with wine lees, broken drinking cups, flat tiles which may have served the purpose of plates, beef and mutton bones, fragments of cooking pots still black from the smoke, and quantities of charcoal. Descending still further, we came upon what appeared to have been a workshop-portions of crucibles in which copper had been smelted, corroded iron, lumps of vitreous glass, broken glass vessels, moulds, and other things being found. Five feet deeper we exposed the excavation in the rock, and a shaft exactly similar to, but on much larger scale than the descent into

the arched tombs. As the hill was removed, platforms were scarped on the sides, on which the earth was thrown up, a man being placed on each platform; and as I descended into the shaft, similar platforms of wood were slung from above. On the twelfth day we reached a depth of 16 feet in the shaft, the portion of the hill removed being 38 feet in length, 20 in depth, and 12 in breadth. The mouth of the shaft hewn out of the rock, 3 feet in thickness, was 18 feet long by 12 broad. It then took on a bell shape, the diameter of which was 22 feet, cut out in dark consistent clay, a depth of nearly 7 feet. Beyond this the size of the shaft became a square seven feet, cut out of successive layers of sandstone and calcareous clay. When we had attained a depth of 30 feet in the shaft, the labour of raising the earth became very great; but by means of a block and shears, which Capt. Commerell, of Her Majesty's ship Snake, very kindly fixed over the descent, the work was much facilitated, the earth being slung up in baskets, and the men ascending and descending in the same manner. A few feet beyond the bones of the horse, and exactly in the centre of the shaft, the skeleton of an adult female appeared enveloped in sea-weed. Under the neck was a lacrymatory, and on the middle finger of the right hand a key-ring. Three feet further we met a layer of human skeletons, laid head to feet, the bones being here in excellent preservation, -as, indeed, we found them to be in all places where the calcareous clay came into immediate contact with them. There were 10 adult male skeletons on this spot, and separated by a foot of clay between each. Five similar layers were found, being 50 in all. I may state that toads in large numbers were found alive in this part of the pit. We had now reached a depth of 42 feet in the shaft, the bones of another horse were turned out, and then we came on loose sand to a depth of 5 feet. Six more skeletons were here again exposed. The sides of the shaft were regular and smooth, the mark of the chisel on the rock being as fresh as when first formed. Six feet more of the loose sand being now taken away, hard bottom could be felt by the steel rod, and there lay two skeletons, male and female, enveloped in sea-weed; and in a large amphora at the corner, which was unfortunately found crushed, were the bones of a child. Some beautiful specimens of pottery, an electrine urn, much broken, lacrymatories, beads and a few coins, were all that I got to repay my labours on this spot. I examined well on every side, and in the rock below, for a trap-door or concealed passage, and an abrupt perpendicular division in the natural strata or layers of calcareous clay appeared to indicate the existence of such, but I found none. Everything during the descent had promised so very favorably, that I fully expected to have found a large chamber leading on from the termination of the shaft; but if such does exist, the discovery of the passage to it utterly baffled all my researches. When the coins I discovered are cleaned, I shall probably be able to fix a date to this wonderful place. The deep fosse, the mode in which the skeletons were found at the bottom, the 5 discovered immediately above these, 50 about the centre, and the bones of the horses, are exactly in harmony with the description of Herodotus of the mode in which the Scythian kings were buried. The substance which I have called sea-weed,  $f_{rom}$  its bearing stronger resemblance to that production than anything else I can compare with it, may possibly be the "grass" described by Herodotus as used to envelope the body. If such be the case, the description is in all respects exact. There was now no time to enter upon fresh explorations.

THE ARCTIC CURRENT AROUND GREENLAND, BY CAFT. IRLINGER, R. D. W. Many hydrographers assert that a current from the ocean around Spitzbergen continues its course along the east coast of Greenland, and thence in a nearly straight line towards the banks of Newfoundland. In this opinion I do not agree. Considerable quantities of ice are annually brought with the current from the ocean around Spitzbergen to the south and south-west along the east coast of Greenland, around Cape Farewell, and into Davis Strait. These enormous masses of ice are frequently drifted so close to the southern part of the coast of Greenland that navigation through it is impossible. To demonstrate the existence of this ice-drift, I may mention the following extract from the log-book of the schooner Activ, Capt. J. Andersen. This vessel belongs to the colony of Julianehaab, and is used as a transport in this district :- 7th of April, 1851, the Activ left Julianehaab, bound to the different establishments on the coast between Julianehaab and Cape Farewell. The same day the captain was forced by the ice to take refuge in a harbour. Frequent snow-storms and frost. On account of icebergs and great masaes of floe ice inclosing the coast, it was impossible to proceed on the voyage before the 23rd, when the ice was found to be more open; but after a few hours' sailing the ice again obliged the captain to put into a harbour. Closed in by the ice until the 27th. The ice was now open, and the voyage proceeded until the 1st of May, when the ice compelled him to go into a harbour. In this month violent storms, snow and frost. From the most elevated points ashore very often no extent of sea visible; now and then the ice open, but not sufficiently so for proceeding on the voyage. At last, on the 6th of June, in the morning, the voyage was continued; but the same evening the ice inclosed the coast, and the schooner was brought into "Blisshullet," a port in the neighboured of Cape Farewell. The following day the voyage was pursued through the openings between the ice; and on the 18th of June the schooner arrived again at Julianehaab. Whilst the masses of ice, as above mentioned, inclosed the coast between Juliannehaab and Cape Farewell, the brig Lucinde crossed the meridian of Cape Farewell on the 26th of April, in lat. 58° 3' N. (101 nautical miles from shore), and no ice was seen from the brig before the 2nd of May, in lat. 58° 26' N., and 50° 9' W. of Greenwich. Further, Capt. Knudten, commanding the Neptune, bound from Copenhagen to Julianehaab, was obliged, on account of falling in with much ice, to put into the harbour of Frederikshaab on the 8th of May, 1852, and was not able to continue his voyage to Julianehaab before the middle of "June, because a continuous drift-ice (icebergs as well as very extensive fields) was rapidly carried along the coast to the northward. Capt. Knudten mentions, that during the whole time he was closed in at Frederikshaab he did not a single day discover any clear water even from the elevated points ashore, from which he could see about 28 nautical miles seaward. Whilst the Neptune was inclosed by the ice at Frederikshaab, the brig Balder, on the home passage from Greenland to Copenhagen, crossed the meridian of Cape Farewell on the 9th of June in lat. 580 9' N. (100 miles from shore) in clear water, and no ice in sight. From the above it is evident that the current from the ocean around Spitzbergen, running along the east coast of Greenland past Cape Farewell, continues its course along the western coast of Greenland to the north, and transports in this manner the masses of ice from the ocean around Spitzbergen into Davis Strait. If the current existed, which the before-named writers state to run in a direct line from East Greenland to the banks of Newfoundland, then the ice would likewise be carried with that current from East Greenland; if it were a submarine current, the deeply-immersed icebergs would be transported by it; if it were only a surface-current, the immense extent of field-ice would indicate its course, and vessels would consequently cross these icedrifts at whatever distance they passed to the southward of Cape Farewell. But this is not the case: experience has taught that vessels coming from the eastward, steering their course about 2° (120 nautical miles) to the southward of Cape Farewell, seldom or never fall in with ice before they have rounded Cape Farewell and got into Davis Strait, which is a certain proof that there does not exist even a branch of the Arctic current which runs directly from East Greenland towards the banks of Newfoundland.

### EXPLORATIONS THROUGH THE VALLEY OF THE ATRATO TO THE PACIFIC IN SEARCH

OF A ROUTE FOR A SHIP CANAL, BY MR. F. M. KELLEY, OF NEW YORK.

Several surveying expeditions have been sent by Mr. Kelley into this region, and much valuable information has resulted. But the chief result is a conviction of the feasibility of a ship-canal through the isthmus. The most recent of Mr. Kelley's explorers, Mr. Kennish, proposes to enter the Atrato by the Cano Coquito. The greatest depth on the bar is about 4 ft. at low water; the soundings gradually deepen and become 30 ft. within 2 miles, when the depth increases to 47 ft., and s nowhere less up to the Truando. The width varies from a quarter of a mile to 2 miles, and the removal of the bar would allow of the transit of the largest steamers. The confluence of the Truando is about 63 miles from the Gulf, and that river forms the channel of the proposed line for 86 miles. The line then follows the valley of the Nerqua through rock-cutting, and passes the summit by a tunnel of  $3\frac{1}{4}$  miles. It reaches the Pacific through the valley of a small stream, and debouches at Kelley's Inlet. In the valley of the Atrato, 300 miles long and 75 broad, and lying between the Antiochian mountains on the east and the Cordillera of the Andes on the west, rain falls almost daily; which accounts for the immense supply of water in that region. On the Pacific side of the Cordillera there is scarcely any rain for eight months of the year. The greater portion of the rain falling in the Atrato valley is caught above the confluence of the Truando. Fifteen large tributaries and numerous smaller streams fall into the Atrato and contribute to the immense lagoons, which form natural reservoirs and a superabundant store of water throughout the year. There are various cogent reasons or selecting the confluence of the Truando as the best point from whence the passage from the Atrato to the Pacific may be effected. In the first place there is no point of junction with the Atrato by western tributaries so near the level of high water on the Pacific as that of the Truando. It happens to be 9 ft. above the Pacific at high water, and it is therefore of sufficient elevation to prevent the Paific at high water from flowing through the proposed cut into the Atrato; while it is not so high as to cause the current from the Atrato to the Pacific at low water to pass through the cut too rapidly. In fact, the elevation of the Truando confuence just preserves a preponderating balance on the side of the Atrato. The Atrato, at the junction of the Salaqui, is only 1 ft. above the level of the Pacific at high water; but the dividing ridge is 1,063 ft. high and 30 miles wide, according o a survey of that route by Mr. Kennish and Mr. Nelson. Should any of the rivers at the mouth of the Atrato be selected, without reference to the height and width of the dividing ridge, it may be observed that the maximum tidal wave in the Paific being 25 ft. and that on the Atlantic only 2 ft., the Pacific at high tide would flow into the Atlantic with a current equal to a head of 111 ft.; and at low water in the Pacific the Atlantic would flow into it with a similar current. In the inlet sf the Gulf of Micuel, recently called Darien Harbour, the action of the tide is so trong, that H. B. M. steamship Virago, commanded by Capt. Prevost, dragged both anchors ahead, and was only brought up by paying out nearly all her cable. The heights of the tides and levels of the two oceans have been well established by the recent observations of Col. Totten in Navy Bay on the Atlantic and in a deep bend of the Bay of Panama on the Pacific. On the Atlantic a consecutive series of thirty-two observations were taken in the months of August and September during the season of calms. On the Pacific two sets of observations were made. The first, during May and June, when fifty-four consecutive tides were observed in a season of calms : and the second in November and December, when fifty-two consecutive tides were observed in a season of light winds. The results do not exactly correspond, and are given in the following table :---

|                                                                   | Pacific.         |                  | Atlantic.         |  |
|-------------------------------------------------------------------|------------------|------------------|-------------------|--|
|                                                                   | May and<br>June. | Nov. and<br>Dec. | Aug. and<br>Sept. |  |
| Greatest rise of tide                                             | 17.72            | 21.30            | 1.60              |  |
| Laget                                                             | 7.94             | 9.70             | 1 0.63            |  |
| Arevere                                                           | 12.08            | 14.10            | 1.16              |  |
| Mean tide of Pacific above mean tide of Atlantic                  | 0.759            | 0.140            |                   |  |
| High spring tide of Pacific above high spring tide<br>of Atlantic | 9.40             | 10.12            |                   |  |
| Low spring tide of Pacific below low spring tide of Atlantic      | 6.22             | <b>9·4</b> 0     |                   |  |
| Mean high tide of Pacific above mean high tide of<br>Atlantic     | $6\ 25$          | 6.73             |                   |  |
| Mean low tide of Pacific below mean low tide of                   |                  |                  |                   |  |
| Atlantic                                                          | 4.73             | 5.26             |                   |  |
| Average rise of spring tides                                      | 14.08            | 17.30            |                   |  |
| Average rise of neap tides                                        | 9.60             | 12.40            | ]                 |  |

These observations make the mean level of the Pacific from 0.14 to 0.75 higher than the mean level of the Atlantic; but this is probably owing only to local circumstances, and it may be assumed that there is no difference in the mean levels of the two oceans. The conclusions arrived at by the successive independent surveys carried out at the expense of Mr. Kelley may be summed up as follows :--First, That the oceans can be united through the Atrato and Truando by a canal without a lock or any other impediment. Second, That while the distance between the oceans by this route is only 131 miles, half that distance is provided by nature with a passage for the largest ships. Third, The remaining distance requires the removal of bars, excavations, and cuttings, presenting no unusual difficulties. Fourth, Harbours, requiring but little improvement to render them excellent, exist at the termini.

### ON ISOTHERMAL LINES, BY PROFESSOR HENNESSY.

The author discusses the distribution of those lines in islands. Considering an island having its shores bathed by a warm oceanic current, the isothermals, if the direct solar radiation were abstracted, would be closed curves surrounding the centre of the island and related to the coast-line, their shapes being variously modified by ranges of mountains, inequalities in the surface, and prevalent winds. By now introducing the effect of solar radiation it follows from the mathematica theory of heat, that the entire quantity of heat received by a unit of surface of

the island will depend on two principal terms: one, a function of the distance of the point from the coast, and capable of being expressed in some cases as a function of the difference of latitude of that point and the nearest point on the coast, and, secondly, of a term depending on the latitude and on an elliptic function of the second order, having for its modulus the line of the obliquity of the equator. The effect of solar radiation will therefore be to transport the centres of all the closed isothermals towards the pole of the hemisphere in which the island lies; and some of these lines may thus ultimately terminate at the coast with their convex sides turned towards the equator, while others may still continue as closed eurres in the interior of the island. The observations collected by Dr. Lloyd in his "Meteorology of Ireland" confirm this theory.

Dr. Lloyd remarked that the influence of the Gulf Stream in elevating the temperature of the coast-stations in Ireland was one of the first results that presented itself in the discussion of the observations referred to, but the inland stations were not numerous enough to form the basis of deduction as to the law of the actual distribution of temperature. He had therefore formed the isothermals from the coast observations, and had compared the inland temperature calculated from these with the observed. This comparison had shown that the effect of the Gulf Stream was even greater than had been anticipated, the temperature over the sea exceeding that over the land by nearly  $4^{\circ}$  Fah, being more than the utmost due to geographical position alone. Hence it was plain that the actual isothermals of a heated sea, cannot be taken as a type of the general phenomena of island temperature. According to Dufresney, the temperature of the sea was generally higher than that of the air above it, but the difference was very small except in the regions of heated currents flowing from a warmer zone.

## ON THE ECLIPSE OF THE SUN IN HERODOTUS.

The Rev. Dr. Hincks has introduced a discussion on the eclipse that Herodotus describes as terminating a battle between the Medes and Lydians. This was supposed by Bayer in 1728, to have been the eclipse of May 18th, 603 B.C., but this view was opposed by Baily in 1811, who argued for the eclipse of Sept. 30, 610 B.C. Baily was, however, confuted by Mr. Hind, who has shown that the shadow would fall nearly  $10^{\circ}$  to the north of Baily's computation, and who falls back on the eclipse of May 28th, 585 B.C. Dr. Hincks conceived this to be an error, and was in favor of the original eclipse of Bayer, viz,—on May 18th, 603 B.C., and intimated a desire to learn what the actual track of this eclipse was according to the most modern tables of the moon.

Dr. Whewell on this remarked that this very eclipse and the whole ground over which Dr. Hincks had travelled had already been fully investigated by the Astronomer Royal in the R. S. Transactions for 1850. M. Bosanquet writes to the *Athenacum* (Aug. 23rd) that "not only the track of the eclipse of 60S B.C. but of every eclipse bearing upon the question between the years 630 and 580 B.C. has been examined by the Astronomer Royal, and the result of his investigations published in the *Phil. Trans.* for 1852, which had been entirely overlooked by Dr. Hincks:" also, that Mr. Hind in 1852 had shewn the eclipse of 585 B.C. to be the only one satisfying all the conditions: that, however, a short time back, the error discovered in Planche's tables had led to a re-calculation of the path for 585 B.C. and the alteration necessary was found to be very slight, so as not to invalidate the conclusion that this must be the eclipse of Herodotus. In reply Dr. Hincks writes to the Aihenævm (Oct. 25) that Dr. Whewell and Mr. Bosanquet are both mistaken: that the paper by the Astronomer Royal in the Phil. Trans. for 1858 contains no calculation for the eclipse of 603 B.C. but only for that of 585 B.C. which latter is inconsistent with known historical facts: the former (603) has never been calculated since Mr. Baily's paper in 1811; and it is known that the tables used by Mr. Baily are defective. Dr. Hineks believes that the error in the mon's longitude introduced by adopting this eclipse will be found consistent with those pointed out by Mr. Adams to exist in Damoiseau's tables, and, after throwing back on Dr. Whewell the imputation of ignorance, again impresses on astronomers the necessity of re-calculating the track for 603 B.C. There the matter rests for the present.

#### THE MOON'S ROTATION.

Mr. Jelinger Symons, one of "Her Majesty's Inspectors of Schools," communicated to The Times not long ago a grand discovery he had made, viz.-that astronomers were all wrong in supposing the moon to have a rotation round its axis. Undeterred by the universal reclamation that assailed him, he brought the subject forward at the British Association, following a paper read by Dr. Whewell on the subject with one of his own, entitled "On Phenomena recently discovered in the Moon." The "recently discovered phenomena" consisted only of his previous assertion, with the addition, that the proper mode of describing the moon's motion was to say that she rotated "round a line, not exactly passing through the earth but near it." He illustrated his position by a machine, which however, was seen. by those capable of analysing its motions, to contradict its author. Unfortunately for himself, this gentleman travelled out of his subject into another department in an incidental sentence, when he stated, as a proof how necessary it was to correct the statements in which philosophers sometimes indulged, that it was now asserted that there were not large assemblages of water upon the moon, whereas Newton has not only traced out her seas, but had actually calculated the heights of the lunar tides-Mr. Symons thus interpreting "lunar tides" to mean tides on the moon instead of tides on the earth caused by the attraction of the moon.

Innumerable illustrations have been given of this motion of the moon for the purpose of rendering this purely geometrical conception familiar to minds not versed in geometry, but we do not remember to have met with the following viz : that a spectator on the moon has just the same reason to attribute a motion round its axis to his moon, as an earthsman has to his earth: for he will find his meridian passing successively through every quarter of the heavens and completing a revolution once a month, just as a spectator on the earth finds his meridian passing through every quarter of the heavens once in a siderial day; the result being in each case the same, namely, an apparent motion of the beavens from east to west completing a revolution, in the case of the earth, in one day, in that of the moon, in one lunation; and, necessarily, the interpretation of such apparent motion being also the same.

VOL. II.-I

# AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

# ( $Concluded_{\bullet}$ )

# ACOUSTICS AS APPLIED TO PUBLIC BUILDINGS, BY PROFESSOR HENRY, OF THE SMITH-SONIAN INSTITUTION.

At the meeting of the American Association, in 1854, I gave a verbal account of a plan of a lecture room adopted for the Smithsonian Institution, with some remarks on acoustics as applied to apartments intended for public speaking. At that time the room was not finished, and experience had not proved the truth of the principles on which the plan had been designed. Since then the room has been employed for two winters for courses of lectures to large audiences, and I believe it is the universal opinion of those who have been present that the arrangement for seeing and hearing, considering the size of the apartment, is entirely unexceptionable. It has certainly fully answered all the expectations which were formed in regard to it previous to its construction.

The President of the United States directed Capt. Meigs to confer with Prof. Bache and myself in regard to the acoustics of the new rooms in the ante-room of the Capitol. Previous to this we first studied the peculiarities of the present hall of the House of Representatives. This is allowed to be one of the worst possible apartments for public speaking; and to determine the cause of the confusion of sounds which exists during debate, is of considerable importance in suggesting improvements in the arrangement of the new rooms. We afterwards examined the principal churches and halls in Philadelphia, New York and Boston, and the peculiarities of these, as far as the investigation extended, may be referred to a few well established principles of sound which have been applied to the construction of this lecture room. To apply them generally, however, in the construction of public halls requires a series of preliminary experiments.

In every small apartment it is an easy matter to be heard distinctly at every point but in a large room, unless from the first in the original plan of the building provision be made on acoustic principles for a suitable form, it will be difficult, and indeed in most cases impossible, to produce the desired result. The same remark may be applied to lighting, heating and vantilation, and to all the special purposes to which a particular building is to be applied. I beg, therefore, to make some preliminary remarks on the architecture of buildings bearing on this point, which, though they may not meet with universal acceptance, will, I trust, commend themselves to the common sense of the public in general.

In the erection of a building, the uses to which it is to be applied should be clearly understood, and provision definitely made for every desired object.

Modern architecture is not a fine art par excellence, like painting or sculpture, the object of the latter is to produce a moral emotion, or awaken the feelings of the sublime or the beautiful, and we egregiously err when we apply their productions to a merely utilitarian purpose. To make a fire screen of Rubens' Madonna, or a candelabrum of the statue of the Apollo Belvidere, would be to debase these exquisite productions of genius, and to do violence to the feelings of the cultivated lover of art. Modern buildings are made for other purposes than artistic effect, and in them the æsthetical must be subordinate to the useful; then the two may coexist, and an intellectual pleasure be derived from a sense of adaptation and fitness, combined with a perception of harmony of parts and the beauty of detail.

The buildings of a country should be an ethnological expression of the wants,

habits, art and sentiment of the time in which they are erected. Those of Egypt, Greece and Rome were intended at least in part, without the art of printing, to transmit to posterity an idea of the character of the periods in which they were erected. It was by such monuments that these nations sought to impress an idea of their religious and political sentiment on future ages.

The Greek architect was untrammelled by any condition of utility. Architecture was with him, in reality, a fine art. The temple was formed to gratify the popular deity. The minutest parts were exquisitely finished, since nothing but perfection on all sides, and in the smallest particular, can gratify an all seeing and critical eye. It was intended for external worship, and not internal use. It was without windows, and entirely open to the sky, or if closed with a roof the light was merely admitted through a large door. There were no arrangements for heating or ventilation. The uses, therefore, to which, in modern times, buildings of this kind can be applied, are exceedingly few; and though they were objects of great beauty and fully realised the intention of the architect when originally constructed, yet they cannot be copied in our days without violating the principles which should govern in architectural adaptation.

Every vestige of ancient architecture which now remains on the face of the earth should be preserved with religious care; but to servilely copy those, and to attempt to apply them to the uses of our day, is as preposterous as to attempt to harmonize the refinement of civilization of the present age with the superstition of the times of the Pharaohs. It is only when a building expresses the dominant sentiment of an age, when a perfect adaptation to its use is joined to harmony of proportions and an outward expression of its character, that it is entitled to our admiration. It has been aptly said that it is one thing to adopt a particular style of architecture, but a very different one to adapt it to the purpose intended.

Architecture should not only change with the character of the people, and in some cases with the climate, but also with the material to be employed in construction. The introduction of iron and of glass requires an entirely different style from that which sprung from the caves of Egypt, the masses of marble from which the lintels of the Grecian temples are formed, or the introduction of brick by the Romans.

The great tenacity, and power of resistance to crushing, of iron as a building material, should point out for it a far more slender and apparently lighter arrangement of parts. An entire building of iron, fashioned in imitation of stone, might be erected at small expense of invention on the part of the architect, but would do little credit to his truthfulness or originality. The same may be said of our modern pasteboard edifices, in which, with their battlements, towers, pinnacles, "fretted roofs and long drawn aisles," cheap and transient magnificence is produced by painted wood or decorated plaster. I must not, however, indulge in remarks of this kind, but must curb my feelings in regard to this subject, since I speak from peculiar experience.

But to return to the subject of acoustics as applied to apartments intended for public speaking. While sound, in connection with its analogies with light, and in its abstract principles, has been investigated within the last fifty years with a rich harvest of results, few attempts have been successfully made to apply these principles to practical purposes. Though we may have a clear idea of the abstract operation of a law of nature, yet when the conditions are varied and the actions multiplied, the results frequently transcend ou rpowers of logic, and we are obliged to appeal to experiment and observation, not only to assist in deducing consequences, but also to verify those which have been arrived at by logical deduction. Furthermore, though we may know the manner in which a cause acts to produce a given effect, yet in all cases we are obliged to ascertain the measure of effect under given conditions.

The science of acoustics as applied to buildings, perhaps more than any other, requires this union of scientific principles with experimental deductions. While on the one hand the simple deductions from the established principles of acoustics would be unsafe from a want of knowledge of the constants which enter into our formula, on the other hand empirical data alone are in this case entirely at fault, and of this any person may be convinced who will examine the several works written on acoustics by those who are deemed practical men.

Sound is a motion of matter capable of affecting the ear with a sensation peculiar to that organ. It is not in all cases simply a motion of the air, for there are many sounds in which the air is not concerned. For example, the impulses which are conveyed along a rod of wood from a tuning fork to the teeth. When a sound is produced by a single impulse, or an approximation to a single impulse, it is called a noise-when a series of impulses, a continued sound, &c.; if the impulses are equal in duration among themselves, a musical sound. This has been illustrated by a quill striking against the teeth of a wheel. A single impulse from one tooth is a noise, from a series of teeth in succession a continued sound, and if all the teeth are at equal distances, and the velocity of the wheel is uniform, then a musical note is the result. Each of these sounds is produced by the human voice, though they apparently run into each other. Usually, however, in speaking, a series of irregular sounds of short duration are omitted-each syllable of a word constitutes a separate sound of appreciable duration, and each compound word and sentence an assemblage of such sounds. It is astonishing that in listening to a discourse the ear can receive so many impressions in the course of a second, and that the mind can take cognizance of and conquer them.

That a certain force of impulse, and a certain time for its continuance are necessary to produce an audible impression on the ear is evident; but it may be doubted whether the impression of a sound on this organ is retained appreciably longer than the continuance of the impulse itself. Certainly not longer than the 1-10th of a second. If this were the case, it is difficult to conceive why articulate discourse which so pre-eminently distinguishes man from the lower animals, should not fill the ear with a monotonous hum; but whether the ear continues to vibrate, or whether the impression remains a certain time on the sensorium, it is certain that no sound is ever entirely instantaneous, or the result of a single impression, particularly in inclosed spaces. Every impulse must give rise to a forward, and afterwards to a backward motion of the atom. The impulse is net only communicated to the ear but to all bodies around, which, in turn, themselves become centres of reflected impulses.

Sound, from a single explosion in air equally elastic on all sides, tends to expand equally in every direction; but when the impulse is given to the air in a single direction, through an expansion taken place on all sides, it is much more intense in the line of the impulse. For example, the impulse of a single explosion, like that of the detonation of a bubble of oxygen, is propagated equally in all directions; while the discharge of a cannon, while heard on every side, is much louder in the direction of the axis; so, also, a person speaking is heard much more distinctly in front than at an equal distance behind. Many experiments have been made on this point, and I may mention those repeated in the open space in front of the Smithsonian Institution. In a circle one hundred feet in diameter, the speaker in the centre and the hearers in succession at different points of the circumference, the voice was heard distinctly directly in front, gradually less so on either side, until in the rear it was scarcely audible. The rates of distance for distinct hearing directly in front, on the sides, and in the rear, were about as 100, 75 and 30.

Those numbers may serve to determine the form in which an audience should be arranged in an open field, in order that those on the periphery of the space may all have a like favorable opportunity of hearing, though it should not be recommended as the interior form of an apartment, in which a reflecting wall would be behind the speaker.

The impulse producing sound requires time for its propagation, and thus depends upon the intensity of repulsion among the atoms; and, secondly, on the specific purity of the matter itself. If the medium were entirely rigid, sound would be propagated instantaneously. The weaker the repulsion between the atoms, the greater will be the time required to transmit the motion from one to the other; and the heavier the atoms the greater will be the time required for the action of a given force to produce in them a given amount of the motion. Sound, also, in meeting an obstacle, is reflected in accordance with the law of light, making the angle of incidence equal to the angle of reflection. The tendency, however, to a divergency in a single beam of sound, appears to be much greater than that in the case of light. The law, however, appears to be definitely observed in the case of all beams that are reflected in a direction near the perpendicular. It is on the law of the propagation and reflection of sound, that the philosophy of echo depends Knowing the velocity of sound, it is an easy matter to calculate the interval of time which elapses between the original impulse and the return of the echo, Sound moves at the rate of 1,125 feet in a second at the temperature of 60 degrees. If, therefore, we stand at half this distance before a wall, the echo will return to us in one second. It is, however, a fact known from universal experience, that no echo is perceptible from a near wall, though one in all cases must be sent back to the ear; the reason of this is that the ear cannot distinguish the difference between the similar sounds, as, for example, that from the original impulse and its reflection, if they follow each other at less than a given interval, which can only be determined by actual experiment; and as this is an important element in the construction of buildings, the attempt was made to determine it, with some considerable degree of accuracy. For this purpose the observer was placed immediately in front of the wall of the west end of the Smithsonian building, at the distance of 100 feet; the hands were then clapped together; a distant echo was perceived, the elapsed time of the passage of the impulse from hand to ear, and that from the hand to the wall and back to the ear was sufficiently great to produce two entirely distinct impressions. The observer then gradually approached the building until no echo or perceptible prolongation of the sound was observed. By accurately measuring this distance, and doubling it, we find the interval of space within which two sounds may follow each other without appearing separately. But if two rays of sound reach the ear, without having passed through distances differing from each other greater than this, they produce the effect of separate sounds. This distance we have called the limit of perceptibility in terms of space. If we

divide this distance into the velocity of sound, we ascertain the limit of perceptibility in time.

In the experiment just made with the wall, a source of error was discovered, in the fact that a portion of the sound returned was reflected from the cornice under the eaves, and as this was at a greater distance than the part of the wall immediately perpendicular to the observer, the moment of the cessation of the echo was less distinct. In subsequent experiments with a louder noise the reflection was observed from a perpendicular surface of about twelve feet square, and from this more definite results were obtained. The limit of the distance in this case was about thirty-five feet, varying slightly, perhaps, with the intensity of the sound and the acuteness of different ears. This will give about one-sixteenth of a second as the limit of time at which the ear can separately distinguish two similar sounds. From this experiment we learn that the reflected sound may tend to strengthen the impression or to confine it, according as the difference of time between the two impressions is greater or less than the limit of perceptibility. An application of the same principle gives us the explanation of some phenomena of sound which have been considered mysterious. Thus, in the reflection of an impulse from the edge of a forest of trees, each leaf properly situated within a range of thirty feet of the front plane of reflection, will conspire to produce a distinct echo, and these would form the principal part of the reflecting surfaces of a dense forest, for the remainder would be screened, and being a greater distance every ray which might come from them would serve to produce merely a low continuation of the sound.

On the same principle we may at once assert that the pannelling of a room, or even the introduction of reflecting surfaces at different distances, will not prevent the echo, provided they are parallel to each other, and situated relatively to each other within the limit of perceptibility.

Important advantage may be taken of the principle of the reflection of sound by the proper arrangement of the reflecting surfaces behind the speaker. We frequently see in churches, as if to diminish the effect of the voice of the preacher, a mass of drapery placed directly in the rear of the pulpit. However important this may be in an æsthetical point of view, it is certainly at variance with correct acoustic arrangements—the great object of which should be to husband every articulation of the voice, and to transmit it unmingled with their impulses, and with as little loss as possible to the ears of the audience.

Another effect of the transmission and reflection of sound, is that which is called reverberation, which consists of a prolonged musical sound, and is much more frequently the cause of indistinctness of perception of the articulations of the speaker than the single echo.

Reverberation is produced by repeated reflection of a sound from the walls of the apartment. If, for example, a single detonation takes place in the middle of a long hall, with naked and perpendicular walls, an impulse will pass in each direction, will be reflected from the walls, cross each other again at the point of origin, be again reflected, and so on until the original impulse is entirely absorbed by the solid materials which confine it. The impression will be retained upon the ear during the interval of the transmission past it of two successive waves, and thus a continued sound will be kept up, particularly if the walls of any part of the room are within thirty-five feet of the ear. If a series of impulses, such as those produced by the rapid snaps of the teeth of a wheel against a quill, be made in unison with the echoes, a continued musical sound will be the result. Suppose the wheel to be turned with such velocity as to cause a snap at the very instant the return echo passes the point at which the apparatus is placed, the second sound will combine with the first, and thus a loud and sustained vibration will be produced. It will be evident from this that every room has a key note, and that if an instrument be sounded on this, it will resound with great force. It must be apparent also that the continuance of a single sound and the tendency to confusion in distinct articulation will depend on several conditions—first, on the size of the apartment; second, on the strength of the sound, or the intensity of the impulse; third, on the position of the reflecting surface; and, fourth, on the nature of the material of the reflecting surfaces.

In regard to the first of these, the larger the room, the longer time will be required for the impulse to reach the wall along the axis; and if we suppose that at each collision a portion of the original force is absorbed, it will require double the time to totally extinguish it in a room of double the size, because the velocity of sound being the same, the number of collisions in a given time will be inversely as the distance through which the sound has to travel.

Again, that it must depend upon the loudness of the sound, or the insecurity of the impulse must be evident, when we consider that the cessation of the reflections is due to the absorption of the walls, or irregular reflection, and that consequently the greater the amount of original disturbance the longer will be the time required for its complete extinction. This principle was abundantly shown by our observations on different rooms.

Thirdly, the continuance of the resonance will depend upon the position of the reflecting surfaces. If these are not parallel to each other, but oblique, so as to reflect the sound, not to the opposite but to the adjacent wall, without passing through the longer axis of the room, it will evidently be sooner absorbed. Any obstacle also which may tend to break up the wave and interfere with the reflection through the axis of the room, will serve to lessen the resonance of the apartment. Hence, though pannelling the ceiling and introducing a variety of oblique surfaces may not prevent an isolated echo, provided the distance be sufficiently great and the sound sufficiently loud, yet that they do have an important effect in stopping the resonance is evident from theory and experiment. In a room fifty feet square, in which the robjects were placed around the wall, its continuance was reduced to two seconds.

Fourthly, the duration of the resonance will depend on the nature of the material of the wall. A reflection always takes place at the surface of a new medium, and the amount of this will depend on the elastic force or power to resist compression and the density of the new medium. For example, a wall of nitrogen, if such could be found, would transmit nearly the whole of a wave of sound in air, and reflect but a very small portion. A partition of tissue paper would produce nearly the same effect. A polished wall of steel, however, of sufficient thickness to prevent yielding, would reflect, for practical purposes, all the impulses through the air which might fall upon it. The rebound of the wave is caused, not by the oscillation of the wall, but the elasticity and mobility of the air. A single ray of sound striking against a yielding board would probably increase the loudness of the reverberation, but not its continuance. On this point a series of experiments were made by the use of the tuning fork. In this instrument the motion of the foot and of the two prongs give a sonorous vibration to the air, which, if received upon another tuning fork of precisely the same size and form, would reproduce the same vibrations.

It is a fact well established by observation, that when two bodies are in perfect unison, and separated from each other by a space filled with air, the vibrations of the one will be transmitted to the other. From this consideration it is probable that very nearly the same effect ought to be produced in transmitting immediately the vibration of a tuning fork to a reflecting body as to duration and intensity, as in the case of transmission through air. This conclusion is strengthened by floating a flat piece of wood in a vessel of water standing upon a sounding board; placing a tuning fork on this, the vibrations will be transmitted to the board through the water, and sounds will be produced of the same character as those emitted when the tuning fork is placed directly on the board. A tuning fork was suspended from a fine cambric thread, vibrated in air, and, from the mean of a number of experiments, was found to continue in motion 252 seconds. In this experiment, had the tuning fork been in a perfect vacuum, suspended without the use of a string, and further, had there been no etherial medium, the agitation of which would give rise to light, heat, electricity, or some other form of etherial motion, the fork would continue its vibration forever.

The fork was next placed upon a large thin pine board—the top of a table. A loud sound, in this case, was produced, which continued less than ten seconds. The whole table, as a system, was thrown into motion, and the sound produced was as loud on the under side as on the upper side. Had the tuning fork been placed upon a partition of this material, a loud sound would have been heard in the adjoining room; this was proved by sounding the tuning fork against a door leading into a closed closet. The sound within was apparently as loud as that without

The rapid decay of sound in this case was produced by the great amount of the motive power of the fork being communicated to a large mass of wood. The increased sound was due to the increased surface. In other words, the shortness of duration was compensated for by the greater intensity of effect produced.

The tuning fork was next placed upon a circular slab of marble, about three feet in diameter and three-fourths of an inch thick; the sound emitted was feeble, and the undulations continued 115 seconds, as deduced from the mean of six experiments.

In all these experiments, except the one in vacuum, the time of the cessation of the tuning fork was determined by bringing the month of a resounding cavity near the end of the fork; this cavity, having previously been adjusted to unison with the vibrations of the fork, gave an audible sound when none could be heard by the unnided ear.

The tuning fork was next placed upon a cube of India rubber, and this upon the marble slab. The sound emitted in this case was scarcely that in the case of the tuning fork suspended from the cambrie thread; and from this anology of the previous experiments we might at first thought suppose the time of duration would be great—but this was not the case; the vibrations continued only forty seconds.

The question may here be asked what became of the impulses lost by the tuning fork? They were neither transmitted to the India rubber, nor given off to the air in the form of a sound, but were probably expended in producing a change in the matter of the India rubber, or were converted into heat, or both. Though the inquiry did not fall strictly within the line of this series of investigations, yet A cylindrical piece of India rubber, about  $1\frac{1}{4}$  inches diameter, was placed in a tubulated bottle with two openings, one near the bottom and the other at the top; a stuffing box was attached to the upper, through which a metallic stem, with a circular foot to press upon the India rubber, was made to pass, air tight. The lower tubular was closed with a cork, in the perforation of which a fine glass tube was cemented; a small quantity of red ink was placed in the hole to serve as an index-The whole arrangement thus formed a kind of thermometer, which would indicate a certain amount of change of temperature in the inclosed air. On the top of the stem the tuning fork was screwed, and consequently its vibrations were transmitted to the rubber within the bottles. The glass was surrounded with several coatings of flannel to prevent the influence of the external temperature. The tuning fork was then sounded, and the vibrations were kept up for some time. No reliable indications of an increase of temperature were observed. A more delicate method of making the experiment next suggested itself. The tube containing the drop of red ink, with its cork, was removed, and the point of a compound wire formed of copper and iron was thrust into the substance of the rubber, whilst the other ends of the wire were connected with a delicate galvanometer. The needle was suffered to come to rest. The tuning fork was then vibrated, and its impulses transmitted to the rubber. A very perceptible increase of temperature was the result. The needle moved through an arc from one to two and a half degrees. The experiment was varied, and many times repeated ; the motions of the needle were always in the same direction, viz : in that which was produced when the point of the compound wire was heated by momentary contact with the fingers. The amount of heat generated in this way is, however, small, and, indeed in all cases in which it is generated by mechanical means, the amount evolved appears very small in comparison with the labor expended in producing it. Jule has shown that the mechanical energy generated in a pound weight, by falling through a space of 750 feet, elevates the temperature of a pound of water one degree.

It is evident that an object like India rubber actually destroys a portion of the sound, and hence in cases in which entire non-conduction is required, this substance can probably be employed with perfect success.

The tuning fork was next pressed upon a solid brick wall. The duration of vibration, from a number of trials, was eighty-eight seconds. Against a wall of lath and plaster the sound was louder, and continued only eighteen seconds.

From these experiments we may infer that if a room were lined with a wainscot of thin boards, and a space left between the wall and the wood, the loudness of the echo of a single noise would be increased, while the duration of the echo would be diminished. If, however, the thin board were glued or cemented in solid connection to the wall, or embedded in the mortar, then the effect would be a feeble echo, and a long continued resonance similar to that from the slab of mable. This was proved by first determining the length of continuance of the vibrations of a tuning fork on a thin board, which was cemented to a flat piece of marble.

A series of experiments were next commenced with reference to the actual reflection of sound. For this purpose a parabolic mirror was employed, and the sound from a watch received on the mouth of a hearing trumpet, furnished with a tube for each ear. The focus was near the apex of the parabola, and when the watch was suspended at this point, it was six inches within the plane of the outer

circle of the mirror. In this case the sound was confined at its origin and prevented from expanding. No conjugate focus was produced, but, on the contrary, the rays of light, when a candle was introduced, constantly diverged. The ticking of the watch could not be heard at all when the ear was applied to the outside of the mirror, while directly in front it was distinctly heard at the distance of thirty feet, and, with the assistance of the ear trumpet, at more than double that distance. When the watch was removed from the focus the sound ceased to be audible. This method of experimenting admits of considerable precision, and enables us to directly verify, by means of sound transmitted through air, the results anticipated in the previous experiments. A piece of tissue paper placed within the mirror, and surrounding the watch without touching it, slightly diminished the reflection. A simple curtain of flannel produced a somewhat greater effect, though the reflecting power of the metallic parabola was not entirely masked by the thicknesses of flannel, and I presume very little change would have been perceived had the reflector been lined with flannel glued to the surface of the metal. The sound was also audible at the distance of ten feet, when a large felt hat, without stiffening, was interposed between the watch and the mirror. Care was taken in these experiments so to surround the watch that no ray of sound could pass directly from it to the reflecting surface.

With a cylindrical mirror with parabolic base very little increased reflection was perceived. The converging beams were merely in this case in a simple plane perpendicular to the mirror, and passing through the ear, while, to the focal point of the spherical mirror, a solid cone of rays was sent.

The reflection from the cylindrical mirror forms what is called a "caustic" in optics, while that from a spherical mirror gives a true focus, or, in other words, collects the sound from all parts of the surface and conveys them to one point of space. These facts furnish a ready explanation of the confusion experienced in the Hall of Representatives, which is surmounted by a dome, the under surface of which acts as an immense concave mirror, reflecting to a focus every sound which ascends to it, leaving other points of space deficient in sonorous impulses.

Water and other liquids, which offer great resistance to compression, are good reflectors of sound. This may be shown by the following experiment:---When water is gradually poured into an upright cylindrical vessel, over the mouth of which a tuning fork is vibrated until it comes within a certain distance of the mouth, it will reflect an echo in unison with the vibrations of the fork, and produce a loud resonance. This result explains the fact, which had been observed with some surprise, that the duration of the resonance of a newly plastered room was not perceptibly less than that of one which had been thoroughly dried.

There is another principle of acoustics which has a bearing on this subject. I allude to the refraction of sound. It is well known that when a ray of sound passes from one medium to another, change in velocity takes place, and consequently a change in the direction or refraction must be produced. The amount of this can readily be calculated where the relative velocities are known. In rooms heated by furnaces, and in which streams of heated air passed up between the audience and speaker, a confusion has been supposed to be produced, and distinct hearing interfered with by this course. Since the velocity of sound in air at 32 degrees of Fahrenheit has been found to be 1,090 feet in a second, and since the velocity increases 1.14 feet for every degree of Fahrenheit, if we know the temperature of the room and that of the heated current, the amount of angular refraction can be ascertained. But since the ear does not readily judge of the difference of direction of two sounds emanating from the same source, and since two rays do not confuse the impression which they produce upon the ear, though they arrive by very different routes, provided they are within the limit of perceptibility, we may therefore conclude that the indistinctness produced by refraction is comparatively little. Professor Bache and myself could perceive no difference in distinctness in hearing from rays of sound passing over a chandelier of the largest size, in which a large number of gas jets were in full combustion. The fact of disturbance from this cause, however, if any exist, may best be determined by the experiment with a parabolic mirror and the hearing trumpet before described.

These researches may be much extended; they open a field of investigation equally interesting to the lover of abstract science and to the practical builder, and I hope on behalf of the committee, to give some further facts with regard to this subject at another meeting.

I will now briefly describe the lecture room which has been constructed in accordance with the facts and principles stated above, so far, at least, as they could be applied.

There was another object kept in view in the construction of this room besides the accurate hearing; the distinct seeing. It was desirable that every person should have an opportunity of seeing the experiments which might be performed as well as hearing distinctly the explanation of them.

By a fortunate coincidence of principles, it happens that the arrangements for ensuring unobstructed sight do not interfere with those necessary for distinct hearing.

The law of Congress authorizing the establishment of the Smithsonian Institution directed that a lecture room should be provided, and accordingly in the first plan one-half of the first story of the main building was devoted to this purpose. It was found, however, impossible to construct a room on acoustic principles in this part of the building which was necessarily occupied by two rows of columns. The only suitable place which could be found was therefore on the second floor. The main building is 200 feet long and 50 feet wide; but by placing the lecture room in the middle of the story a greater width was obtained by means of the projecting towers.

The main gallery is in the form of a horse shoe, and occupies three sides of the room. The speaker's platform is placed between two oblique walls. The corners of the room which are cut off by these walls afford recesses for the stairs into the galleries. The opposite corners are also partitioned off so as to afford recesses for the same purpose.

The ceiling is twenty-five feet high, and therefore within the reach of perceptibility. It is perfectly smooth and unbroken, with the exception of an oval opening near the platform, through which light is admitted.

The seats are arranged in a curved form, and were intended to rise in accordance with the papoptic curve originally proposed by Professor Bache, which enables every individual to see over the head of the person immediately in front of him. The original form of the room, however, did not allow of this intention being fully realised, and therefore the rise is rather less than the curve would indicate. The general appearance of the room is somewhat fan-shaped, and the speaker is placed as it were in the mouth of an immense trumpet. The sound directly from his voice, and that from reflection immediately behind him, is thrown forward upon the audience, and as the difference of the distance travelled by the two rays is much within the limit of perceptibility, no confusion is produced by direct and reflected sound. No echo is given off from the ceiling, for this is also within the limit of perceptibility, while it assists the hearing in the gallery by the reflection to that place of the oblique rays.

Again, on account of the oblique walls behind the speaker, and the multitude of surfaces, including the gallery pillars, stair screens, &c., as well as the audience, directly in front, all reverberation is stopped.

The walls behind the speaker are composed of lath and plaster, and therefore have a tendency to give a more intense though less prolonged sound than if of solid masonry. They are also intended for exhibiting drawings to the best advantage.

The architecture of this room is due to Captain Alexander, of the Corps of Topographical Engineers. He fully appreciated all the principles of sound which I have given, and varied his plans until all required conditions, as far as posssible, were fulfilled.

### CANADIAN INSTITUTE.

#### Session-1856-57.

FIRST ORDINARY MEETING-Saturday, 6th December, 1856.

E. A. MEREDITH, Esq., LL.B., Vice President, in the Chair

The following Gentlemen, provisionally elected by the Council during the recess, were Balloted for and declared duly elected Members ;

> A. T. AUGUSTA, Esq., Yonge St., Toronto, KOBT. ARMOUR, Esq., Bowmanville, C. W. ISAAC BUCHANAN, ESq., Hamilton, C. W. JAMES BROWN, Esq., Toronto, C. W. J. BEATTY, JUDR., Esq., M. D., Cobourg, C. W. G. G. BIRD, Esq., M. D., Bowmanville, C. W. REV. R. G. Cox, Wellington, P. E. District, C.W. ED. FITZGERALD, Esq., Toronto, C. W. A. J. FERGUSSON, Esq., M.P.P., Guelph, C. W. REV. ROBT. IRVINE, D.D., Hamilton, C.W. EDGAR J. JARVIS, ESQ., Toronto, C. W. REV. PROFESSOR KENDALL, Trinity College, Toronto, C. W. REV. J. LAING, Scarborough, C. W. H. H. MEREDITH, Esq., Port Hope, C. W. DAN. McLELLAN, Esq., Hamilton, C. W. JOHN MCBRIDE, Esq., Toronto, C. W. REVD. D. PIERCE, Kingston, C. W. J. P. RUSSELL, Esq., M.D., Quebec, C. E. J. W. TATE, Esq., Belleville, C. W W. G. TOMKINS, Esq., C. E., Hamilton, C. W. MAJOR F. WELLS, 1st Royal Regiment of Foot. REV. W. S. DARLING, TOronto, C. W. HOD. L. T. DRUMMOND, M. P. P. Montreal, C. E.

WILLIAM HEWSON, Esq., Whitby, C. W. R. SANDARS, Esq., Trinity College, Toronto, C. W. DR. CHARLES SEWELL, Toronto, C. W. J. F. SMITH, Toronto, (Junior Member).

The donations to the Library and Museum received since the last ordinary meeting, were laid upon the table. The Secretary was instructed to include a record of them in the Annual Report, and to communicate the thanks of the Institute to the Donors for their valuable contributions.

Professor Cherriman gave the requisite notice of motion of an amendment to Regulation 4. Sec. II., touching the amount payable to constitute Life Membership; and Dr. Wilson to Regulation 1. Sec. VII., for the addition of a third Vice-President to the office bearers in accordance with the terms of the Charter.

The following Papers were read:

1. By Capt. William Kennedy:

"On the proposed expedition to the Arctic Regions in further search of the records or remains of Sir John Franklin."

2. By the Rev. W. A. Adamson, D.C.L.:

"On the decrease, restoration, and preservation of the Salmon in Canada."

SECOND ORDINARY MEETING-13th December, 1856.

JAMES BOVELL, M. D., Vice-President, in the Chair.

The following Gentlemen were elected Members :

THOMAS M. CLARK, Esq., Toronto.

HON. JAMES PATTON, M.A., Barrie, C. W:

BEVERLY ROBINSON MORRIS, Esq., M. D., Toronto.

W. LORING CILLERY, Esq., Toronto.

WILLIAM SHIRREFS, Esq., Toronto.

A. S. KIRKPATRICK, Esq., Toronto.

CHRISTOPHER PATERSON, Esq., Barrister, Toronto.

The following Donations were then announced, and the thanks of the Institute voted to the Donors :

From the Secretary of the School of Mines, Paris:

Annales des Mines, 5e Serie, Tome VI. 5e Livraison de 1854-55.

Do. do. VII. 1re, 2e, 3e Livraison de 1855.

From the Regents of the University *ex officio* Trustees of the State Library, in behalf of the State of New York.

Documents relating to the Colonial History of the State of New York. Vols. III., IV. and VII.

Annual Report of the Trustees of the New York State Library, 22nd January, 1856.

Science and Religion—Sermon delivered in Albany during the Session of the American Association for the advancement of Science: by the Rev. Bishop Hopkins, D.D.

Montreal in 1856, a Sketch prepared for the Opening of the Grand Trunk Railway of Canada ; Pamphlet.

From Rev. J. M. Phillippo, per Prof. Croft-

Transactions of the Society of Arts, Jamaica, for year 1854-5.

The following Communications were read:

1. By Professor Chapman:

"A description of some Trilobites found at Whitby; illustrated by specimens." 2. By James Gilbert:

"On the Arizura Copper Mine, accompanied with specimens of Ore from the California Mines."

The requisite nominations of office-bearers for the ensuing year were made, and the Vice-President announced that on the following Saturday, the Annual General Meeting would take place at Seven P. M., to receive the report of the Council, elect the officers and members of Council for the ensuing year, and for other business.

ANNUAL GENERAL MEETING -Saturday, 20th December, 1856.

E. A. MEREDITH, LL.B., Vice-President, in the Chair,

The following Gentlemen were elected Members :

HUGH THOMSON, Esq., Toronto,

JAMES W. DUNSFORD, Esq., Verulam, C. W.

CHARLES F. GILDERSLEEVE, Esq., Toronto.

WILLIAM BALDWIN SULLIVAN, Esq., Toronto.

JOHN HEAD, Toronto. (Junior Member.)

The following Communications were read:

1. By Professor Croft, D. C. L.,:

" Notes on the Oxalate of Manganese."

2. By Joseph Robinson, Esq., :

"On a Process for Preserving Timber from Decay."

3. By James Bovell, M. D., :

" On Cell Developement."

4. By R. T. Pennefather, Esq., :

"Notes of a Journey made by Governor Simcoe, from Niagara to Detroit, in 1793."

Prof. Cherriman, in accordance with previous notice, moved :

That Rule 4, Sec. II., shall be amended by erasing the sum of  $\pounds$ 7 10s. and substituting therefor  $\pounds$ 10, as the sum payable by Members for Life— Carried. Dr. Wilson, in accordance with previous notice, moved :

That in Rule 7, of Section II., the words "and third" be added after "second" so as to admit of the election of a third Vice-President in accordance with the provisions of the Charter.—Carried.

The Report of the Council for the year 1855-56, was then read as follows :

ANNUAL REPORT OF THE COUNCIL, 1856.

The Council of the Canadian Institute have the honor to submit the following Report of the proceedings of the Institute during the past year.

The Council have the highest satisfaction in announcing that upwards of one hundred and fifty names have been added to the list of Members since the date of the last Annual Report, and that the accessions thus made to the numerical strength of the Institute indicate not only local, but widely spread interest and co-operation.

The total number of Members of the Institute now amount to five hundred, of whom it may be interesting to note that there are: 370 residents of Toronto, 162 of other parts of Upper Canada, 33 of Lower Canada, and 10 Foreign Members: thus establishing the Institute as provincial rather than local in its character.

The Council have continued to make such additions to the Library by purchase as the funds at their command would seem to justify; and they trust that those additions, comprising nearly one hundred volumes of completed Works—independent of periodical literature—will commend their efforts in this particular to the approval of the Institute.

The Council have great pleasure in submitting the list of Donations made to the Library during the past year, indicative not only of extended interest in this important branch of our efforts, but illustrating continued and very remarkable liberality on the part of Donors to whom the Institute had before been largely indebted. Although anxious to avoid invidious references where so many are entitled to the acknowledgments of the Institute, the Council are warranted in particularly noting the generous contributions of the Honorable J. M. Brodhead of Washington, a valuable donation, including 25 volumes; of Mr. Bohn of London, England, including 58 volumes; and of Dr. Chewett of Toronto, including 57 volumes; to each of whom the Institute is especially indebted for large and very valuable additions to its collection, of a class of works peculiarly suited to the objects which the Institute is chiefly designed to promote. By the various additions thus made to the Library, its value for the purposes of reference has been considerably increased, and it now embraces a collection of upwards of seventeen hundred volumes, the great majority of which are of a scientific or practical character.

In the last annual Report for the year 1855-6, the Council expressed their regret that no addition to the Museum had been made during the year then closing. It is therefore with greater satisfaction that the Council have now to acknowledge the receipt of contributions:—the list of which, embracing various specimens in Geology and Natural History, and a small collection of fifty-five silver coins, including those of Edward II., III., and VI., and Queen Elizabeth, will be enumerated in the classified catalogue,—not only because of the value attaching to these donations, but as justifying the hope that the collection may be early augmented to a standard of usefulness. The practical value of such collections depends so largely on facility for reference, that members of the Council have engaged in the preparation of classified catalogues of the Library and Museum—and such measures have been taken as warrant the assurance that these will be completed for use during the present session.

The Council have further to announce that, in fulfilment of the conditions annexed to the acquisition of the valuable library of the Athenaum, referred to in last Report, arrangements have been effected under which the public may visit and consult the Library of the Institute daily between the hours of three and five o'clock; and that a book has been opened wherein Members are invited to enter the title of any weak which they recommend to the Council for purchase.

By these measures it is hoped that the Library, already of very considerable value, may become of more direct and continuous utility to our members and the public at large, whilst the interest thus excited may direct attention, not only to its possessions, but to its deficiencies, and thus may result in increasing and more general efforts in aid of its extension, as well as in the augmentation of the Institute's collections of specimens of Natural History, Minerals, and other objects of scientific inferest and value, so as ultimately to render both the Library and Museum creditable to the Institute and beneficial to the Province at large.

In submitting the list of communications read at the meetings of the Institute during the session, 1855-56, the Council are gratified in being able to note that, whilst the number of papers read last year was largely in excess of that reported for the preceding session, the proportion emanating from the general body of Members of the Institute, as distinguished from Members of the Council, has also been considerably augmented : an evidence of growing co-operation which the Council regard as most important and satisfactory; and giving promise, as they trust, of still further and more effective manifestation of activity during future Sessions.

In view of the successful character of the Canadian section of the Exhibition of the Industry of all Nations at Paris, in 1856, and especially of that portion of it entrusted to Sir Wm. Logan : and of the honors which had been conferred upon him by Her Majesty, by the Emperor of the French, and by the learned Societies of England and France, the Institute determined to accord such a welcome on his return to Canada, and such congratulations on his well-earned and richly merited dignities, as would be fitting, from this Society to him as its first President, and expressive of the esteem in which he is held by its Members.

The necessary preliminary measures having been taken, Sir William Logan was invited to be present at a meeting of the Institute held on the 5th April, 1856—when an address of congratulation was presented to him by the President, G. W. Allan, Esq. This address, together with the reply of Sir Wm. Logan, have already been recorded, and published in the Transactions of the Institute; and, together with a portrait of him by which its rooms are now adorned, remain as enduring mementos of the appreciation of the Society of the services which he has rendered to Science, and the honor and benefits he has conferred on Canada by his successful researches as a practical Geologist.

Attached hereto will be found the Report of the Editing Committee nominated by the Council to conduct the Canadian Journal—submitting a statement of their proceedings during the past year, and their views in reference to the important duty entrusted to them.

To that document the Council desire to direct the special attention of the Institute—and in doing so to congratulate its members on the steady and increasing success of the publication, which they feel justified in regarding as the most essential and promising element of the future prosperity and usefulness of the Institute.

The scheme for a New Series of the Journal submitted in the last Annual Report, and subsequently authorized by the Institute, has been carried into effect with, as the Council venture to believe, very satisfactory results.

The public criticism of the work has been favorable, its form has been approved as convenient, and its circulation has increased, while the expense of its publication is considerably reduced. Much of this is undoubtedly due to the high character which attached to the earlier series of the Journal, the experience gained by its issue, and the excellent basis thus formed for the more mature work; yet much is also to be attributed to the services and indefatigable zeal of the General Editor, Dr. Wilson, under whose direction the work has been issued, along with the valuable and effective co-operation of his coadjutors, of whose joint labors the Members have already enjoyed abundant opportunities of judging for themselves.

The practice adopted by the Council in reference to the former series of the Journal, of placing it in the hands of the trade for general sale, having been found to be attended with much trouble, without any adequate advantages to repay the care of looking after booksellers' accounts, and the returns of agents for copies on sale, the Council have adopted the practice-usually acted upon by Scientific Societies at Home, with their Transactions,-of printing the Journal exclusively for distribution among the Members of the Institute, and such Institutions and Societies as they may transmit it to in gift, or exchange for their publications. As the annual payment of four dollars from Members resident in Toronto, and of three dollars from country Members, is not more than the Journal of the Institute may be considered fully worth,-in addition to the other advantages which resident Members enjoy,-this arrangement has in no degree checked the increasing circulation of the Journal, while it has materially contributed to the large addition of new Members above referred to. The only exception which the Council have deemed it advisable to make to this rule is, that Members are permitted to purchase additional copies, and Provincial Literary and Scientific Societies to subscribe for the Journal by an annual payment in advance, at the same rate as the subscription required from non-resident Members.

The experience of the Council during the past year has fully confirmed them in the wisdom of this course, and they accordingly recommend that it be adhered to, and that the new series of the Journal be continued and permanently adopted in its present form; and they have much satisfaction in announcing that Dr. Wilson has consented to continue his services as Editor in Chief during the ensuing year. With a view to meet the rapidly increasing numbers of the Institute, the Council instructed the Editing Committee to increase the new edition of the Journal from even hundred and fifty—the number of the former series—to one thousand copies; of these about six hundred and fifty have been distributed, and the remainder are in reserve to meet the demands consequent on the future extension of the Institute, and the exchanges which its rapidly extending relations with foreign Societies may require.

## EDITING COMMITTEE'S REPORT.

The Committee appointed to edit the new series of the Canadian Journal, beg leave to submit to the Council the following Report of their proceedings during the past year.

In accordance with the instructions of the Council, as set forth in the scheme prepared and published in the Annual Report for 1855, the duties of the Editing Committee were classified and divided among its members.

The organization of this Committee having only taken place at the close of last year, and their duties being further complicated by the transfer of the printing of the Journal to a different firm from that formerly employed, some delay necessarily took place in the first number; and difficulties were occasioned to the Editing Committee on more than one subsequent occasion by impediments entirely beyond their control, such as the want of the requisite fonts of type, especially for some of the scientific papers of a special character. But these and other obstacles to

### CANADIAN INSTITUTE.

the regular publication of the Journal are now, it is hoped, no longer likely to interfere with its issue at the appointed periods.

From the Treasurer's accounts it appears that the entire cost of printing the Journal for the year 1856, including illustrations, postages, &c., for an edition increased to one thousand copies, amounts to £257 0s.  $9\frac{1}{2}d$ .\* and in reference to this your Committee would only draw attention to the fact that nearly the whole of the matter being original, printed from the authors' manuscripts, and subject to their revision and corrections, it is mainly owing to the exertions of those Editors of the various sections who have gratuitously superintended the correction of the press, that this source of former outlay no longer occurs; but that, on the contrary, a considerable increase in this department of necessary expenditure has been avoided.

In the six numbers for 1856, constituting the first volume of the New Series of the Canadian Journal, twenty-nine original papers have been printed, twenty-four of which have been selected from the communications made to the meetings of the Institute during last session. Of the twenty-three Reviews accompanying these, twenty have been contributed by members of the Editing Committee; and they have much pleasure in acknowledging the valuable services rendered to them, and to the Institute, by the contributions of the Rev. Professor Young, and Professor Buckland to this department. In carrying out the fourth head of the scheme adopted for the new series of the Journal, which required "all matter derived from published sources, to be printed in small type, and to form a distinct division or appendix," your Committee have appended to each number a section entitled SCIENTIFIC AND LITERARY NOTES; but it will be found that only a small portion of this is borrowed from published sources. It has already, on more than one occasion, embodied the first notice of original discoveries or observations, and has regularly included translations and careful abstracts on one or more branches of Science, from Home and Foreign Journals; so that your Committee venture to hope this section of the Journal will be regarded by many of its readers as not the least valuable of its contents.

The Editing Committee earnestly invite contributions from the members at large. The departments of Natural History, Geology and Mineralogy, Natural Philosophy, and Engineering, might be greatly enriched by short notices derived from personal observation, throughout the various districts of this widely extended Province; and to all the sections of the Journal it must be in the power of many members to furnish additions of general interest and value. For those which embrace subjects connected with the Ancient Races and the early historical monuments of this Continent, communications are specially desired. Probably no season passes over without the disclosure of some remains of the Aboriginal possessors of the land, accompanied with evidences of ancient arts, customs, or sepulchral rites; and it is a matter of great moment, and calculated to confer a permanent value on the Journal as a book of reference, that such should be accurately noted and recorded as they occur. The same observations apply to the Fauna and Flora of the Continent, which are unquestionably disappearing from many localities, now encroached upon by the clearings of new settlers : and

<sup>•</sup> The difference between this statement of the actual cost of the Journal, in the Report of the Editing Committee, and that embodied in the Treasurer's Report, arises from the latter charging the Journal, as in former years, with one-half of the Assistant Secretary's salary

concerning the former habitats of which, notices put on record now, will hereafter possess an ever increasing value. Further, the Editing Committee would urge on all the members of the Canadian Institute the duty of aiding to secure the communication of materials requisite to make this periodical alike creditable to the Society and useful to the Province.

In thus summing up their first year's labors, and inviting future co-operation, it is with sincere regret that the Committee have to record the loss to the Institute, as well as to themselves, of two esteemed coadjutors, whose services have contributed to the interest of the Journal during the past year. The recall of Captain Noble, R. A., by whom the admirable Meteorological Reports have hitherto been furnished for Quebec, will, it is feared, bring that valuable series of returns to a close; while in the resignation by the Rev. G. C. Irving, of the Chair held by him in Trinity College, Toronto, and his subsequent departure for Europe, the Editing Committee, and the members of the Institute at large, have lost a fellow-laborer, whose absence will long be felt to create a blank in their meetings.

DAN. WILSON, COnvener.

Toronto, November 1, 1856.

When the Council assumed office, they, with the Members of the Institute generally, indulged the hope that during the past summer some progress might have been made in the erection of the new building; when, however, they came to consider in detail the provision which must necessarily be made, the expenditure which it involved, and the entire insufficiency of the funds at command to secure such progress as would justify active measures during the season, they were reluctantly compelled to abandon any attempt to proceed with the structure during the present year. The calls upon the public from other quarters had been so pressing and continuous, that the Council feared the prosecution of their appeal for aid under the circumstances would have been productive of injury to the scheme. They preferred therefore rather to await a more promising opportunity for calling in subscriptions, than to urge their claims at a period which such efforts as they made abundantly manifested to be so unpromising; and they were further induced to this decision, by the reflection that whilst the funds already in their
possession would continue to fructify, they might confidently rely upon additions to them by future Parliamentary Grants, as well as by the increased liberality of individual subscribers when less intruded upon by rival appeals. Having then secured such amount as will suffice for the objects in view, they anticipate the time as not far distant when the Institute may engage in the work free from the risk of debt, and without the apprehension of the depressing and perhaps disastrous influence which such could scarcely fail to have on the Institute.

The Council trust that these views will meet with the entire concurrence of the Members of the Institute, and that the motives by which they were governed in adopting, after the most anxious and mature deliberation, the course of procedure here referred to, may stimulate the members and friends of the Institute to such active co-operation and liberality in their contributions as will justify the construction of the building during the ensuing summer, and enable the successors of the present Council, in presenting their next Report, to congratulate the Members on its speedy completion, if not to present it to them, assembled in their own Hall.

# F. W. CUMBERLAND,

Secretary.

Toronto, 6th December, 1856.

# AUDITOR'S REPORT, 1856.

We, the undersigned, beg to report to the Council of the Canadian Institute, that we have examined the Cash Book and compared the Vouchers with the items of expenditure recorded, which agree. There appears to be a Balance in the Treasurer's hands of ninety-one pounds five shillings and sevenpence currency, and invested by the Treasurer, upon securities exhibited to us, one thousand three hundred and eighty-nine pounds six shillings and eightpence.

> J. STEVENSON, HERBERT MORTIMER, Auditors.

Toronto, 9th December, 1856.

The Report was unanimously adopted.

The Chairman having appointed Mr. Sheriff Jarvis and Mr. S. Fleming as scrutineers, the ballot for Election of Officers for the ensuing year was proeseded with, and

The following Gentlemen were declared duly elected;

President, the Hon, Chief Justice DRAPER, C. B.

| 1st Vice President,      | Professor E. J. CHAPMAN.   |

### Also,

" Blatta and 1 Hymenopterous Insect—exotic.

THIRD ORDINARY MEETING .- 10th January, 1857.

The Hon. Chief Justice DRAPER, C.B., President, in the Chair.

The following Gentlemen were elected Members: ROBERT SNELLING, Esq., Toronto. Rev. Saltern Givens, Yorkville. Alex. Manning, Esq., Toronto. JAMES GRAND, Esq., Toronto. WILLIAM PROUDFOOT, Esq., Hamilton. SAML. H. STRONG, Esq., Toronto. GEO. F. DUGGAN, Toronto, (Junior Member.)

The following Donations to the Library and Museum were announced, and the thanks of the Institute voted to the Donors:

From the Author:

1

Sketch of the Montreal Celebration of the Grand Trunk Railway of Canada, by W. Baldwin Sullivan, Esq.

From the Hon. J. M. Brodhead, per A. H. Armour, Esq.,:

"United States Japan Exhibition, vol. III."

"Patent Office Reports, 1855."

From the Author, per A. H. Armour, Esq., :

"An Overland Journey round the World in the years 1841, and 1842," by Sir George Simpson.

From Phillips, Sampson & Co.:

"Prescott's Robertson's History of Charles V.," three volumes.

"Religious Truths, illustrated from Science," by E. Hitchcock, D.D., LL.D. From John Head, Esq.:

" A large Stone Gouge."

The President's ANNUAL ADDRESS was delivered by the Hon. Chief Justice Draper, C.B.

The following Paper was then read:

1. By the Rev. Professor Hincks:

"On Cell Developement."

This communication, containing some strictures on a paper on the same subject read by Professor Bovell at the previous meeting, and Professor Bovell not being present, it was ordered to be transmitted to him for the purpose of affording him an opportunity of further discussing the subject.

FOURTH ORDINARY MEETING .- 17th January, 1857.

The Hon. Chief Justice DRAPER, C.B., President, in the Chair.

The following Gentlemen were elected Members:

ROBERT P. CROOKS, Esq., Toronto.

T. C. WALLBRIDGE, Esq., Belleville.

JAMES JOS. WOODHOUSE, ESq.,

WILLIAM ANDERSON, Esq., Toronto.

Edward Hurd, Esq., Toronto.

AUGUSTUS HEWARD, Esq., Montreal.

EDWARD D. ASHE, Esq., R. N., F.R.A.S., Quebec.

JOHN CRICKMORE, Esg., Toronto.

WILLIAM HAMILTON, Esq., Toronto.

The following Papers were then read :

1. By Col. Baron de Rottenburg :

"Observations on the General Telescopic aspect of the Five Primary Planets, including the Planet Mercury."

2. By JOHN LANGTON, Esq., M, A. :

"On a Small Wave hitherto undescribed."

3. By Prof. D. WILSON, LL.D. :

" On the Mediæval Pageant of the Dance of Death."

Professor Wilson called the attention of the Institute to the great loss sustained by the scientific world in the late painful death of the distinguished Geologist, Hugh Miller. He bore a gratifying testimony to the character and personal worth of the deceased Geologist, and to his earnest and self-sacrificing devotion to the science with which his name will ever be honorably associated, and in the too ardent pursuit of which his life has been made a sacrifice. MONTHLY METEOROLOGICAL REGISTER, AT THE PROVINCIAL MAGNETICAL OBSERVATORY, TORONTO, CANADA WEST-DECEMBER, 1856.

te Barometric range for this month (2.021 inches) is the greatest yet recorded at the Observatory. A very remarkable range within 12 hours (1.014 inches) oc-eured from midlight of the 13th to noon of the 14th.

e Rain and Snow were both in excess of the average; the former by 0.251 inches.

and the latter by 1.9 inches. ind. This was the most windy December since the commencement of the series, giving a mean velocity of 3.83 miles above the average of 9 years. are resultant direction and velocity for December from 1848 to 1856, was N 75° W

2.88 miles per hour.

# NOTES OF TRAVEL IN CHINA.

BY JAMES H. MORRIS, M.A.

Read before the Canadian Institute, March 14th, 1857.

A residence of little more than three months in China would not justify me in giving expression to opinions on the polity, government, resources, or commercial interests of a country, whose limits extend over an area of 5,300,000 square miles, and whose population is equal to one-third of the human family. Nevertheless the observations of a recent visitor may not be devoid of interest, now when the peculiar circumstances of our relations with China, naturally direct an unusual amount of attention to that country. I shall accordingly confine my paper to that part of the country which has recently been the scene of the warlike operations of the British fleet, and will endeavour to give some idea of the singular people with whom it has had to contend.

During the existence of the south west monsoon, vessels bound to China by way of the "Cape of Good Hope," generally shape their course for the China Sea through the straits of Sunda; and after one has for many weeks felt the ennui consequent on a long sea voyage, the imagination is apt to paint in supernatural beauty the long anticipated scene. But there are favorite spots where nature exhibits herself decked in such charms as to defy the overcolouring of fancy, and among such are the straits of Sunda.

At the entrance to the straits between the Islands of Java and Suma-

VOL. II.-L

tra, and in close proximity to Java, where various clustering isles adorn the scene, attention is specially attracted by an immense irregularly shaped island named "Princess Island," thickly studded with different kinds of trees which perfectly conceal the soil or naked rock from the view.

The sinuous coast of Java, however, presents a different appearance; craggy cliffs strike upwards, whose rugged faces bear the marks made by the lashing of the surge; high irregular hills in the distance whose sides are begirt with native plants, and whose tops taper to a point and hide themselves in the clouds; a sloping beach of easy access and overhung by outspreading branches which cast a shadow over the water, appearing to invite the stranger to it: far receding bays over whose surface are wafted on the breeze spicy odours from the home of the savage; and an array of cocoa nut trees extending for miles along the strand, and exhibiting from the tops of their slender trunks the tempting fruit: all add to the variety of the scene; while the majestic Banyan stands alone and affords a shady retreat for hundreds of Malays, who there seek amusement, comfort or repose.

Quantities of different species of fruit, consisting of mangustines, oranges, lemons, mangos, pine apples, and vegetables of many kinds; as also live representatives of the mixed inhabitants of the jungle: monkeys, moose deer, red and green parrots, mocking birds, sparrows, &c., are brought by the natives in canoes to passing vessels, and offered for sale.

Passing through this "Eden of the East" in a fortnight, our proximity to our destination was evinced by the appearance of high and naked islands, around which could be seen ill-shapen and odd rigged craft, which were soon recognized to be Chinese fishing boats. Off the "Lema Islands," among which is to be seen the conspicuous peak of Hong-Kong, vessels are boarded by a native pilot. Some of their boats carry foreign flags, (principally English and American,) and others the private flags of different mercantile houses, which are vouchers of the respectability of the parties who carry them. Their boats average about fifteen tons burthen and are seldom manned by less than four men. There is no necessity for a vessel to reduce her speed for these men, unless she is exceeding six or seven knots per hour, for they can always succeed in getting on board. They run down across the ship's bows and bring their boats near enough to the ship, to enable them to reach her chains with a long bamboo pole, by means of which they fasten on a grapple secured to the end of a long rope: This rope they pay out so as to prevent the sudden

impetus which is given to their boat from swamping her, and when she has assumed a tolerable degree of steadiness, the pilot pulls himself up along side and clambers over the sides of the vessel. He presents his credentials for inspection, which generally conclude with an averment that "the bearer is as honest as any Chinaman," and the terms for pilotage being agreed upon, which can invariably be reduced to one half the demand made, a few pieces of junk or salt beef, are thrown over into the pilot's boat, in accordance with the custom of the country, and it is then cast off. The Harbour of Hong-Kong, called Victoria harbour, at all times presents a very happy appearance; it is about five miles in length, and from one to three in width, hemmed in by islands and mountainous lands so as to resemble a small lake. Steamers of war, sloops and frigates, lie at anchor for the protection of the commerce of the countries they represent, and are among the first vessels which the observer distinguishes from the hundreds, including the native craft, each contributing to the variegated scene which the collection of flags presents. One could easily imagine that they were all lying in readiness to bombard the city, on a signal being given, for every sea-going vessel exhibits from her sides an array of mounted guns, many of which are superstitiously decorated by the Chinamen with pieces of red cloth.

The Island of Hong-Kong was ceded to Great Britain at the conclusion of the war with China by a treaty made in 1842, and though heretofore an expensive appendage to the British Crown, it is hoped that ere long it may become a valuable acquisition to her possessions east of the Cape of Good Hope.

Being a free port, vessels going to China on speculation, with or without a cargo, make Hong-Kong their place of destination, as they escape all harbor dues and other expenses which would be imposed on them were they to go to any other port. Sometimes they remain several weeks before they find a market for their commodities, or procure freight for the homeward passage, and this delay entails on them a certain expense by which the colony is benefitted.

The Island is about twenty-five miles in circumference, very mountainous, and yielding very little produce. The city of Victoria is upwards of three miles in length and some of the buildings are large and handsome. The principal public ones are the English Church, Government House and Government Buildings, the Barracks, and Club-houses, which are of granite and expensively furnished. From the commanding position which they occupy, they give the place a solid and wealthy appearance. Many private residences, extending up the sides of the mountains as far as prudence sanctions. ornament the rear of the city. The streets are wide and well filled with Chinamen, among whom are intermingled people from every quarter of the globe. Some of the gay scarfs and variegated turbans of the Hindoos, as contrasted with the bare shoulders of the natives of the country, add much to the novelty of the picture. The buildings of the tradesmen are of wood, two stories high, the lower part being entirely open and in design reminding one of butchers' stalls. At night closely fitting shutters are put up. The rent of these places being high, if the lessee is not in good circumstances he frequently invites within his narrow limits two or three other tradesmen of different pursuits, who carry on their business independently of each other, but contribute an equal proportion towards the payment of the rent. A portrait painter, a tailor, and a shoemaker form a trio: a copper-smith, a tin-smith and an umbrella maker also affiliate; a hatter and a watchmaker, a haberdasher and a vender of ivory curiosities, and others of equally. opposite pursuits, are seen working together. As many workmen are required to enable their masters to fulfil their engagements, all of whom are huddled together in this single room, which answers. the purposes of workhouse, warehouse and shop: their numbers. disincline a customer to go beyond the threshold, but he has such. articles brought to the door as he desires to examine with the view. of making a purchase.

Between the southern limits of the city and the Barracks, is a large public reserve of several acres which is much frequented by idle Chinamen, who resort thither to while away the day by gambling and sleeping. Peripatetic barbers and itinerant pastry cooks. migratory venders of medicine, and wandering booksellers, strolling fruiterers and roving conjurors, fill up the interval, and the unnatural sounds which some of them bellow forth in recommendation of their articles strike harshly on the ear of the foreigner. Passing along the general thoroughfare will be seen groups of Chinamen, some wearing long blue gowns reaching down to their feet and exhibiting from below a pair of dark cloth shoes, with paper soles of an inch in thickness. One hand is uplifted and holds between the sun and the head of the Chinaman, an open fan or out-spreading umbrella, while the other is engaged in twirling and lashing against his sides, the celebrated queue which is dearer than life itself. The hair is shaven off the head excepting on the crown, from which it is allowed to grow as long as nature will permit it, but the Chinaman above the order of coolies, (which are the lowest and most degraded class in the Empire,) universally plaits into it heavy skeins of silk, which terminate within two or three inches of the ground. Others dressed only to such an extent as places them without the rigour of the law, and who are styled "coolies," wander about prepared to work if well paid, to steal, which they prefer doing, if an opportunity offers, or to join in any disturbance that may arise. These fellows are watched pretty closely by the police, who treat them with well merited severity when they detect them in the gratification of their unlawful cupidity. When brought before the police magistrate, he enrols them among the chain gang, who make and repair the public roads, and are thus rendered generally useful. This corps is distrbuted every morning throughout different parts of the town, each detachment being in charge of a policeman who holds a musket over one shoulder, and an open umbrella on the other.

There are several villages in Hong-Kong, and on the adjacent islands, the inhabitants being principally piratical fishermen, who, no doubt act in collusion with the more desperate outlaws who hoist the flag of their profession.

Excursions are constantly made by the police force and volunteers in Hong-Kong, against the piratical fishermen, and when prisoners are taken they are bound together by their queues and led to the prison. Sometimes they are handed over to the authorities at Canton. under whose direction they are decapitated. The population of the whole island is upwards of 45,000; the foreign residents, exclusive of the military, numbering about 300 persons. The floating part of the population in front of the city is large. This class of people exists throughout China, and is a separate race in itself. They are born, marry, and live out their existence, in their shell-like abodes. Many of them procure employment from foreign ships, each one while in the harbor having one or more native boats attached to her. Those generally patronized are about 18 feet in length, and carry sails made of matting. They are entirely decked over with closely fitting boards, and when a passenger presents himself, three or four in the centre of the boat are taken up to make room for his legs, the surrounding portion being neatly matted over and serving as a seat. The cabin into which the legs only are admitted, is floored and matted, the flooring being about two and a half feet from the deck; and resting on the left side of the boat will be seen a little idol sitting in senseless state, and which the occupants of the boat never fail to worship, both in the morning and evening. Every boat throughout the Empire, no matter how small, is provided with its tutelar deity, before which are displayed josssticks, wax tapers, and "chow-chow," or food, which is served up in small dishes, and consists of cold tea, and different species of fruit; but the loss of appetite which this uncomplaining favorite invariably manifests, if not a matter of wonder to its indulgent devotee, is at least an occasion of profit. Over head is a cylindrical frame-work covered with double matting, the inner one being made of straw, and the outer of split rattan. It protects the inmates of the boat from the tropical sun, or pelting rains which are very frequent.

The cooking takes place in the after part of the boat, each one being provided with a stone or earthenware portable kitchen, which rests between the decks, and is covered over in wet weather, or when the smoke becomes disagreeable to those on board.

The other parts of the boat are used as lockers, store-rooms, or sleeping apartments; in fact, the Chinamen sleep all over the boat, as often on deck as below: a Chinaman's bed consisting merely of a mat and split rattan pillow. Should the night be cold, instead of wrapping themselves up in blankets, they put on one suit of clothes over the other until they feel comfortable. It is a common sight on a chilly day to see a Chinaman with all his wardrobe on at once, and presenting a portly appearance with which nature never endowed him.

The boats carry one or two masts and large sails made of matting, both of which are lowered on deck when they cannot be used.

The oars are composed of two pieces of wood, the blade being bound to the loom by means of cords. At the upper end of the loom is a transverse piece of wood about five inches in length and one in diameter, which is used as a handle, and on which the oarsman can have a good purchase. Instead of row locks, there are pins about fifteen inches in height, generally having a slight curvature in them, and graduated by notches, from one of which a small loop of straw rope is suspended, through which the oar is thrust.

Sometimes the Chinamen sit down on the deck and pull as Europeans do, but their custom is to stand up facing the bow of the boat and work the oar from the shoulder. The women labor as hard as the men, and in nearly every boat will be observed one or more having an infant slung on to her back, which is rocked to sleep by the exertions of its mother.

The appearance of the children is disgusting. No attention is paid to their sanitary condition, and they are allowed to grow up without appreciating the detersive property of water. Their play mates are cockroaches, which although they exceed them in numbers are less offensive in the sight of a foreigner. Their food, which is called "Chow-Chow," consists of boiled rice, sweet potatoes and greens, as also fish, with which they are generally well supplied. Boiled rice is the standing dish, and it is no uncommon sight to see one person consume amongst other things, from half a gallon to a gallon of rice at one meal. The rice is placed in a pail on the deck and surrounded by the greedy participators, each one having a bowl in his hand which he fills with rice, and when he has arranged the chop-sticks in his fingers, their application commences most vigorously. The bowl is held up to the mouth and the rice is shovelled in until nature demands an intermission of a few seconds to recover respiration. The idea which suggests itself on first seeing them, is that each is trying how much more he can consume than his neighbour, within a certain stipulated time.

Some of the occupants of the poorer description of craft, which slightly resemble the punts used in this country, or as a Chinaman would say "all same, leete more diffilent," are less fastidious in their tastes than those in better circumstances, and will eat anything that can be digested. Hourly they may be seen plucking the hair from a dead rat which has been thrown to them from a foreign ship, or there may be heard the last of what was an animal of the same tribe, singing his farewell song on the frying pan, and sending forth his savoury odour on the breeze.

A peculiar style of boat characterizes each province, though differing immaterially in internal economy; but the reader can form a fair idea of all of them from the foregoing description.

At a distance of 70 miles from Hong-Kong, in a northerly direction is the city of Canton. It lies on the north side of the Pearl River, up which the traveller is conveyed on an European steamer which plies between the two places. This river varies in width from a quarter of a mile to several miles, and though to a certain degree destitute of that natural grandeur which characterizes some of the rivers of America, it is not without its attractions.

It leads into a country where the christian is abhorred; which was five centuries ago as far in advance of European nations in the arts and civilization as they are now her superiors; which until compelled by the British bayonet, refused to recognize England or America as among the civilized countries on the globe, or to admit within her kingdom foreign officials on terms of equality; whose empire has been usurped by a Tartar tribe, the chief of which has ever had the power of nominating his successor, who styles himself the "Viceregent of Heaven upon earth," and who by establishing arbitrary laws which are rigidly enforced, and by practising deceit, stratagem, and tyranny, governs a people naturally docile, and maintains his supremacy.

About midway between the mouth of the river and Canton, are the "Bogue Forts" which were captured by the British during the war of 1842, and which command such a range that they appear to guard the threshold of the Empire. Here the channel begins to narrow, and the hills rise to a great height on either side. Mounted batteries line the beach, and forts in design not unlike the Greek letter omega, are built in more elevated positions. They were in a state of decay when I saw them, and the few guns which looked from the embrasures were red with rust: but by recent accounts we learn that they have since been repaired, only to be destroyed by the British. At the summit of the hills are square formed watch towers of granite, from which a signal could be given to the ports below when an enemy approaches. An island situated further up the stream and at an angle of  $45^{\circ}$  with the Forts on shore, is also strongly fortified.

If nature did as much for the security of some enlightened countries as she has done for China, the science and ingenuity of the people would contribute such acquisitions to the natural strength, as would render the place impregnable.

A circumstance is related which happened at the "Bogue Forts," during the war of 1842, truly characteristic of the Chinese : but before mentioning it it is necessary to remark that in every part of China which has been visited by foreigners, the attention of the traveller is early arrested in consequence of the incessant noise which the natives keep up by the clang of gongs, the beating of drums, the shrill notes of the flute, the explosion of packages of fire crackers, and the confusion of tongues; this medley not tending in any degree to impress upon the mind of the unaccustomed hearer, the conviction that the Chinese have a predilection in favor of quiet.

Owing to the severity of the penal code, such a sight as an assault made by one Chinaman on the person of another is seldom or never seen, but disputes continually take place followed by angry countenances, rapid contortions of the body, and tirades "full of sound and fury," but "signifying nothing."

The commander of the Forts understanding that the British fleet was about to make an attack upon the garrison, sent off an officer in a boat with a letter to the British commander. The interpreter whose dialect will be noticed hereafter, translated it as follows: "These two piecie nation must makey fightie, spose that yankilish man no put shot in he guns, Chinaman no put shot in he guns, makey noisey all same !"

At the distance of about ten miles from Canton is the village of Whampoa, where the foreign shipping lies at anchor, the cargoes of the different vessels being brought down to them from the city in native boats. The steamer passes through a long line of frame and bamboo houses built upon piles, and which are rather difficult of access when the tide is on the ebb.

19

Two celebrated pagodas are among the first objects of attraction, but their design and the object of their erection have been so frequently described by travellers, that further reference to them is unnecessary. The river between Whampoa and Canton is very narrow: on the opposite sides, embankments are thrown up to prevent the river from over flooding the paddy fields. The country on either side is under a high state of cultivation, and in whatever direction one chooses to look, from the mountain top to the valley below, on the face of the hills and over the plains, there cannot be seen one single foot of eligible soil which has escaped the tillage of the industrious Chinaman. The hills and mountain sides when practicable are terraced and prolific with sweet potatoes.

When near to Canton the number of native craft begins to increase in the channel, and the pilot stands in the bow of the steamer waving his hand in every direction as a warning to his countrymen to keep out of the way. Accidents occasionally happen which can only be attributed to the temerity or stupidity of the sufferer. The boatmen take their own time to retreat, and sometimes risk running across the bows of the steamer rather than to wait for a few seconds until she passes—happening every trip the steamer makes, it becomes very trying to the temper of the pilot and others belonging to her, who sometimes hurl a well directed missile at the craft which has approached within such an offensive proximity.

The appearance of Canton from the river is very unprepossessing, the foreign factories, the only buildings of any importance having been recently destroyed by fire. While they stood, with the beautiful gardens in front of them, over which were flying the different foreign flags, there was an aspect of comfort characterising at least a portion of the suburbs of the city which existed not within the walls.

No steeples nor domes rise up in the distance, no sloping hills crowned with solid edifices adorn the prospect, no smiling grounds surrounding a happy looking abode lie on the water side, no widestretching avenue opens to the view the heart of the city, no wharves nor esplanades, but one gloomy plain of dark and decaying roofs fills up the space between the river and the mountains. A few forts not meriting a description, a couple of pagodas not particularly elegant, an occasional group of trees, and official poles standing before the residences of a mandarain, and which an author has likened to "dismantled gallows," can be seen from an eminence, but their variety gives but little relief to the sombreness of the picture.

The foreign merchants, (by which I mean the British, French and American,) were confined to a few acres of ground on the river side, which were tastefully laid out and filled with different species of trees and plants.

About one hundred yards from the water were the Hongs, or Factories in which they reside and transact their business. These buildings were three stories high, and presented a long frontage filling up latitudinally the prescribed limits. They extended some distance in depth, it being customary in China to build houses of this description in rear of each other, all being accessible by means of an arched passage which runs underneath them. Between each building, in the rear, was an area of a few feet square. These houses appeared as if built beneath a common roof; it was impossible to avoid the unwilling gaze of a neighbour into the opposite bed room, kitchen or dining room, unless by closing the blinds which would have impeded the free circulation of the air, and have made the matter worse.

The hospitality which strangers receive from foreigners throughout China is proverbial, as all travellers in the country can testify : while in addition to this their acts of generosity to strangers in distress lead one to believe that the old-fashioned virtues of charity and benevolence are not yet extinct, but exist in patriarchial simplicity wherever they are most needed.

In the foreign gardens was a neat Episcopalian Church, a Club House, and a collection of boats equal to those in any other part of the world. The city proper is surrounded by a high wall, within which no foreigner is admitted. The gates are thrown open during the day, and through the archway, a glimpse can be had of the prohibited city. After once passing through a Chinese street there are no inducements to go a second time. There are two in the neighbourhood of the factories occupied by the foreigners, from which strangers usually make their purchases. These are about ten feet in width, and are always crowded with men and women, some having boxes of tea suspended from either end of a bamboo staff which rests on the shoulders; others packages of paper similarly carried. Starved looking cats, whose melancholy mew betokens their impending fate, are carefully secured in cages, and puppies whose keepers hold them up to the view, are ready for the dainty epicure. Expatiating booksellers, apothecaries vending their drugs to their hypocondriacal customers, and trained birds whose feats astonish the rabble, fill up the interval. This confused mass must be buffetted with, in attempting to pass through a street in Canton.

Signs innummerable, projected from one to three feet from the front of the houses, and suspended lengthwise, are adorned with gaily painted characters, which tell the name of the merchant before whose door they hang. The shops are rather dark inside, but many of them are filled with an excellent assortment of silks, ivory wares, Chinese devices, and foreign importations. The plausibility and naivette of the merchants, and in fact of every Chinaman with whom the stranger comes into contact, are very apt to achieve the purpose for which they are assumed, unless he has been previously fortified against them by one whose experience has been dearly purchased, and who wishes to save a friend from the imposition which would be practised upon him. They are an artful and untruthful race, who by smiles and complimentary addresses invite the passing stranger beneath their roof that they may rob him. They hesitate not to tell an untruth, and blush not at being detected, and the oldest foreign residents in China, freely say that the more respectable the appearance of the man, or exalted his position among his fellow men, the greater is the necessity for doubting his sincerity. No moral principle regulates their action in life, interest alone compels them to perform their agreements with the foreign residents, having been taught that they will not be patronized unless they are upright in their dealings with them. They ask the stranger five times as much for an article as they would be ultimately willing to take for it.

The shopmen, and in fact, nearly all the tankia or boat people in the neighborhood of the foreign gardens, speak a corruption of the English language, commonly called "pigeon English," *pigeon* being the Chinese mode of pronouncing "business."

This language has become a regular dialect, and when first heard by the stranger it would appear as though the person speaking was parading indiscriminately, a few English words before his hearer whose duty it was to make a meaning out of them. A foreign resident will introduce a friend to a Chinese merchant as follows: "mi chin-chin you, this one velly good flin belong mi, mi wantchie you do plopel pigeon along he all same fashion along mi—spose no do plopel pigeon, mi flin cum down side mi housie, talke mi so fashion mi kick up bobbery along you." To which the Chinaman will reply: "mi savey no casion makey flaid, can secure do plopel pigeon long you flin all same fashin long you."

Fighting with crickets is a common amusement among the Chinese, and the belligerents can be purchased in small cages. A foreigner wishing to ask for a cricket will say: "mi wantchie makey look, see those two pieces ting makey fightie."—"Haiyah hab got can catechie chop-chop," will be the Chinaman's reply.

This language is as simple as it is absurd, but the words must be arranged as the Chinaman has been accustomed to hear them, or he will not understand what is said. It is spoken in all the ports of China open to foreign trade, and there is no disposition to adopt a purer one. No matter how fluently the China merchant may speak this "pigeon English," he cannot understand anything that is spoken among the foreigners themselves; and this is on the whole fortunate, as remarks are daily made at table about the country and its institutions, which would not be at all gratifying to a mandarin to hear.

The majority of the streets are very narrow, and it would not be a difficult matter for a person to get by one single step from one side to the other. Most of the retired streets are occupied by tradesmen, those of a similar calling keeping together and occupying a whole side of a street. A long row of houses solely occupied by shoemakers, will be seen on one side, and on the other side an equal number of tailoring establishments or trunk makers, all of whom are hard at work. One would fancy that it would be to the interest of all parties were they to distribute themselves throughout the city. but it is to be inferred that they each have patrons who find out their favorite link in the long chain, and visit no other. In many of the streets are to be seen shops containing goods of foreign manufacture, and there are many other indications of the benefits which the Chinese are deriving from foreign intercourse. Ugly looking implements of torture standing in racks, and under the custody of policemen, occupy a position in every street, their disreputable guardians being a greater source of dread to the people than the polished steel itself. The police are poorly paid by the Government, and make up the deficiency by practising enormities upon the people, which dare not be introduced into any civilized country. They are complained of at times by the people, but no heed is given to their petition, unless it is accompanied by a certain amount of money which the sufferer is unwilling and in most instances unable to furnish.

Licensed beggars walk the streets, some of them in a most pitiable condition. This class of the community elects a chief man, who, during his supremacy, is responsible for the misconduct of any of his subjects, and aids the government in detecting any who have infringed the laws of the Empire. They are allowed to frequent all public places and thoroughfares, and would be intolerable, were it not for a custom which exists among the respectable foreign and Chinese houses of paying a monthly sum to the head man, which exempts the donors from the importunities of the vagrants. This is the only method of evading them, and so well disciplined are they, that they seldom approach those whom they have been instructed to avoid.

It is customary amongst the Chinese to have public exhibitions in the streets, which are paid for by private subscription, and which give the people something to talk about for several days. On occasions of this kind the streets are roofed over from one end to the other, and chandeliers and gaily painted lanterns, are suspended from the rafters. Along the sides of the streets are arranged trained plants, some representing a deer and kid, others birds, pagodas, and sundry other devices, all of which indicate the ingenuity of the Chinese.

At either end of the street stages are erected, which are occupied by theatrical performers, tumblers, jugglers, and musicians: hundreds of wax tapers are lighted within the street, and on looking through it from the entrance it has a most dazzling appearance.

On crossing the river between the main land and the island of Honam, (which lies opposite the foreign factories,) at ebb tide illshaped looking rocks shoot up in the stream, on which will be seen groups of Chinamen washing, or rather destroying clothes. Instead of using a board or rubbing the linen between their hands, as civilized washerwomen do, these fellows twist the articles into ropes and thrash away on the pointed rocks, each blow taking more than a week's wear out of the garment. When anything requiring particular care is given to them, they beat it between two stones, which soon find their way through it, much to the displeasure of the owner.

Some of the Hongs occupied by the Chinese tea merchants, are substantial brick and stone buildings, and considering their locality, imbedded as they generally are in the centre of a densely inhabited part of the city, are airy and comfortable. They are approached by means of an archway, or warehouse, a door opening from it into the street. These places are used for the stowage of tea, which is brought down from the country. Within these warehouses are dezens of active Chinamen busily engaged in putting matting on the boxes which are intended for exportation. At the extreme end is the Hong of the merchant, the rooms on the ground floor being used for offices and reception rooms, while those on the upper story are the private apartments of the household. Throughout the private hall up stairs are distributed tables and chairs of a very costly description, the wood work being of a dark colour similar to ebony, very massive and richly carved. On the top of each is inserted a marble slab suitable to the purpose for which it is designed.

On either side of the hall is a row of chairs and small tables alternately arranged, so that each guest when seated has a separate table to himself. A cup of tea is invariably handed to a visitor with the leaves lying in the bottom of it. The cups are very small, and the Chinese drink the infusion without using either sugar or milk. In the rear of the houses, and in some cases in front of them is a flower garden shaded by fruit-bearing trees, beneath which the wife or wives, and children of the Chinaman are permitted to walk. The female portion of the community are never visible. Canton is the capital of the province within which it lies, and being the oldest place in the empire open to foreign trade, people from all quarters of the globe are pushing their fortunes within its precincts.

The natives are treacherous towards foreigners and troublesome to the Government, and the seditious can be seen undergoing punishment in the public streets. For petty offences a man is thrashed through the streets. Men sentenced to wear the cangue, or moving pillory, often fill up the way, and their sorrowful countenances are indices of their suffering. The cangue weighs about fifty pounds, and is composed of heavy planks about four feet square, in the centre of which is a hole large enough to allow the neck to work with ease when this collar is placed on it. The prisoner is allowed to go at large, and is fed solely by the hand of charity. His name and the nature of his offence, are written on the front of the cangue. It is just wide enough to prevent him from lifting his hand to his mouth. to walk is distressing, to lie down impossible, so these poor wretches are worn out by fatigue and end their life by the way side. But the reckless indifference of the Chinese to the value of human life is well known. During the year 1855, upwards of eighty thousand heads were cut off in Canton alone.

Situated at the distance of about sixty miles from Canton in a westerly direction, is the Island of Macao, which is under the respective jurisdiction of the Portuguese and Chinese Governments. Portugal has had a lease of part of the island for the past two centuries, which will continue so long as the yearly rent is paid. In former days, and during the existence of the East India Company's charter, Macao was the head quarters, in China, of that honorable body, and the improvements which they added to the place by the erection of superior buildings and the general adornment of the neighbourhood are still to be seen, but divested of their original attractions. The city lies between two hills, on a peninsula stretching forth from the island, and its breadth is only about a quarter of a mile or very little more; a current of cool air is continually circulating through it, which makes it a place of resort during the hottest months in the year. The Portuguese population is under the direction of a Governor who has a few soldiers allowed to him, to enable him to keep the place in subjection, and prevent the encroachments of the Chinese. A wall is built across the island. the Chinese Mandarin having his residence in the village on one side of it, and the Portuguese Governor his abode on the other. Each has exclusive jurisdiction over his own countrymen, and when a subject of one domain renders himself amenable to the laws of the other, he is transferred to his own Government to undergo his trial and receive his sentence if convicted. On the tops of the hills are extensive forts which perfectly guard the city from attack on any The buildings erected by the East India Company are quarter. located on the south side of the island, at a short distance from the beach, and give the place a pleasing appearance from the water. They give a frontage to the city between the hills, and form an agreeable contrast with the spires and domes which rise up in their rear. Parallel with the beach is a wide level road called the "Prava Grand," at the eastern extremity of which is a park. This is resorted to on Sunday afternoon, by the whole community, to enjoy the delightful music which the military band is generously discoursing, with a view to dispel any gloom that might have arisen during the religious exercises of the morning.

There are two Roman Catholic Churches in Macoa, and as there are no seats in either of them, the female worshippers sit down on the floor, each having brought a small woollen mat, which she throws down on the spot she has selected. The women wear gay muslin or calico dresses, and a cambric shawl which is drawn up over the head in lieu of a bonnet

Nearly all the principal foreign merchants in Canton, have furnished houses in Macao which they visit in hot weather. They are kept up for the benefit of the young men in their employment, who after a busy season are permitted to take a few days to themselves, which can be more agreeably passed in Macao than elsewhere. So great is the variety of fish in the waters surrounding Macao, that according to the statements of old residents, there is a separate fish for every day in the year.

Since the expiration of the charter of the East India Company, Macao has been gradually declining, but she would have revived during the wsr between England and China, in 1842, had not a spirit manifested itself which defeated its own object. At that time foreigners were obliged to leave Canton, and take up their abode and transact their business on this island, and all foreign vessels resorted to its harbour. If instead of imposing heavy duties on foreign commodities, and harbour dues upon the shipping, the port had then been free, Macao would not have been obliged to transfer to Hong-Kong, the short lived distinction which circumstances involuntary granted her. Her rulers now feel the weakness of their policy, which evinces its effects in the harbour, the streets, and the buildings. Only native craft disturb her waters, the streets are desolate, and many of the India Company's Hongs are untenanted. Those merchants who have private residences at present, will not retain them after their lease expires, and thus by the short sighted policy of the governing powers of Macao, other islands are destined to outnumber her in population, and exceed her in wealth. Nevertheless. Macao must still be a place of interest to every foreigner, and sacred in the memory of Portugal. Her pure air and solitary retreats were once enjoyed by an exile, who conscious of his wrongs, still restrained the pen of calumny, and painted in immortal verse. the glory of his fatherland. The cave of Camœns, in which was composed a portion of the famous Lusiad, can be seen on this island; and when the stranger looks upon the cenotaph erected in its centre by order of the country which had exiled him,-calling to rememberance that the mighty spirit of the poet in whose honour it was tardily reared, had perished in the streets of Lisbon, driven forth by hunger, neglect and sorrow; and that no finger can point to the resting place of Portugal's greatest hero; he loses all sympathy for the oppressor in contemplating the sufferings of the victim, and feels that this,-like so many other national tributes to genius,-is rather a memorial of the nation's shame.

# ELECTRIC TELEGRAPH FOR PREDICTING STORMS.

# ON THE EMPLOYMENT OF THE ELECTRIC TELE-GRAPH FOR PREDICTING STORMS.

# BY G. T. KINGSTON, M.A.,

PROFESSOE OF METEOROLOGY, UNIVERSITY COLLEGE, AND DIRECTOE OF THE MAGNETIC OBSERVATORY, TORONTO.

Read before the Canadian Institute, 24th January, 1857.

The employment of the Electric Telegraph for transmitting intelligence relative to the Meteorological conditions that prevail at the same instant, over a wide area of country, is an application so obvious, that it is not surprising that it should have occurred to the minds of many. A few years since an arrangement was in existence in England, by which Mr. Glaisher at Greenwich, received by telegraph, daily reports, at a certain hour, of the state of the wind and weather from various localities in England, Ireland, and Belgium, and there is, I believe, a similar system at the present time in operation, with its centre at the Exchange in Liverpool.

The general idea then involved in the present communication is not new; but this circumstance, though it destroys any claim to originality, possesses at least this advantage, that members of the Institute who may be called on either to reject the following suggestions, or to co-operate in carrying them into effect, will take up the matter with minds somewhat prepared for the task, by previous experience and reflection.

Not to occupy time with further preliminary remarks, I shall proceed at once to state briefly the general nature of the scheme that I have to propose.

That the annual loss by shipwreck, of property, (not to say life,) in the American lakes is considerable, there can be no question. The Lake Association of underwriters on the American side, estimated, the loss during the season just closing as over FOUR MIL-LIONS OF DOLLARS; and it will be found, I have little doubt, that the loss on the British side is proportionably great. It should be remembered further that these losses' whatever they may be, other things remaining the same, will increase with increasing commerce. I have not at command any statistics relative to the loss of shipping on the rivers and sea coasts; nor is it essential that I should produce such; since the general fact without precise numerical data, is a sufficient basis for that which is to follow.

There can be no question but that many shipwrecks would be prevented, if vessels in port had timely notice of a coming gale.

VOL. II.-M

# 178 ELECTRIC TELEGRAPH FOR PREDICTING STORMS.

Ships intending to remain would make preparations requisite for withstanding it; and those about to sail would either postpone, or hasten their departure.

Admitting then that wrecks are numerous, and that their number, as well as that of many minor disasters, might be materially diminished if gales were commonly foreseen, I go on to consider the means, *first* of procuring the necessary intelligence; and *secondly* of transmitting that intelligence to the shipping.

On the latter object, the *transmission* namely of intelligence, it is not necessary to dwell, since for this purpose the ordinary machinery of the telegraph is sufficient; and I may therefore confine my attention to the object first named, that of *procuring* the information requisite for the prediction of an approaching storm.

The possibility of doing this depends on the truth of the two following statements, the first of which is certain, and the second highly probable.

1. That gales prevail in some localities often many hours, sometimes two or three days before they reach other places only a few hundred miles distant.

2. That storms in their progress are subject to definite laws, which extended observation will discover.

Assuming the object to be practicable, I propose to effect it by an arrangement of which the following is a rough sketch:

With the concurrence of the telegraph companies, the operator at each of certain specified stations in British North America, should have orders to send immediate notice to the telegraph office at Toronto, of the commencement of a gale at his station. On receiving such a message, the operator at Toronto would call the attention of the Observatory by an alarum, or other contrivance; then repeat the message and connect the observatory wires with those from the various selected stations. The Observatory would then issue orders for hourly or half-hourly returns, or make such occasional enquiries as might be thought expedient.

The information thus collected would supply the data from which to derive a knowledge of the laws that govern the progress of storms, and if these laws were understood, would enable the central office to send notice to the ports along the lake and sea coast, and the various districts through which the storm was about to pass, of the probable time of its arrival, the quarter from which it might be expected, and its approximate duration.

I do not anticipate that the expenses attending such an arrange-

ment would be heavy; but at any rate I feel certain, that if it were carried into successful operation, the expenses would be covered a thousand fold by the saving to life and property that it would occasion. To enter at present into further details, would I think be premature; I therefore leave the matter for the Institute either to take up or to reject.

# REPORT OF THE COMMITTEE ON PROFESSOR KING-STON'S PLAN FOR PREDICTING STORMS.

Read before the Canadian Institute, 14th March, 1857.

The Committee of the Council of the Canadian Institute, to whom was referred Professor Kingston's paper on the application of the Electric Telegraph, in giving intimation of storms ocurring at different localities, present the following Report :

The Committee consisted of Baron de Rottenburg, Professor Croft, and Professor Cherriman; in addition to whom they had the assistance of Professor Kingston, and of Mr. Alexander, telegraph operator.

The Committee recommend that Professor Kingston's paper be printed, and a letter be addressed, with a copy of the paper, to the several Boards of Trade and Insurance Offices in the Province, with a view of securing their co-operation in carrying out the objects the Professor has in view; and suggesting to these bodies the advisability of their entering into some agreement with the several Telegraph Companies, to defray the expenses of forwarding the necessary telegraphic messages from one station to another, and also to the magnetic observatory at Toronto; and whenever these arrangements shall be completed, that a letter be addressed to the Secretary of the Province, to obtain for the Magnetic Observatory the services of an additional assistant, as a telegraphic operator, and that authority shall also be demanded to defray the expenses of laying down wires from the observatory to the telegraph office.

The telegraph stations which appear to the Committee to be favourably situated for the transmission of notices of storms which may occur in the localities, or for forwarding such notices from other places are as follows, viz:

| Halifax, N. S.,  | Fredericton, N. B., |
|------------------|---------------------|
| Riviere du Loup, | Quebec,             |
| Three Rivers,    | Montreal,           |
| Ottawa City,     | Prescott,           |
| Kingston,        | Cobourg,            |
| Toronto,         | Hamilton,           |
| Port Dalhousie,  | Port Colborne,      |
| Port Dover,      | Windsor,            |
| Sarnia,          | Goderich,           |
| Collingwood,     | Barrie.             |
|                  |                     |

Availing themselves of the experience of Mr. Alexander, in reference to the probable expense of the necessary telegraphic messages, the Committee are led to believe that this would not exceed  $\pounds 200$  annually; and Mr. Alexander suggests, that it would be desirable for the Insurance Companies to insert in policies of Insurance hereafter, a clause obliging captains and owners of vessels to make inquiries at stations, from which their vessels are about to sail, whether any storm is raging at the time in the direction of their course; and that if this was done, and the expenses of such messages or information were paid for by said captains or owners of vessels, it would lessen the expense.

DE ROTTENBURG, Convener.

# ON AN OCCULTATION OF SPICA VIRGINIS BY THE MOON.

BY COLONEL BARON DE ROTTENBURG.

Read before the Canadian Institute, 4th April, 1857.

The following brief remarks upon the Planetary appearance of Stars of the 1st and 2nd magnitudes, on the night of the 12th March, 1857, when taken into consideration along with the accompanying notes of independent observations, on the occultation of Spica Virginis by the moon, on the morning of the 13th March, will not, I trust, be deemed unworthy of the attention of the members of the Canadian Institute. The first of these does not indeed possess in itself sufficient importance to warrant its forming the subject of a particular communication, but when it is regarded in connection with some unusual, though not unprecedented appearances seen in the occultation of the star Spica at the same time, and it is considered that possibly the same optical or atmospheric causes may have exercised more or less influence on both phenomena, I have been induced to bring both matters before the Institute.

With reference to the planetary look of the stars, of the 1st and 2nd magnitude, as observed by me on the night of the 12th March, (a night not easily forgotten, having been that on which the terrible railroad accident occurred at the Desjardins Canal bridge.) I saw that bright star in Lyra, (Vega,) with a disc like the planet Jupiter; this was about one o'clock on the morning of the 13th. I could scarcely believe it was not a new star, so brilliant was its appearance, till I satisfied myself of its identity; I then observed the other stars of the 1st and 2nd magnitudes which were visible, viz. other stars of the 1st and 2nd magnitudes which were visible, viz. Arcturus, Regulus, Procyon, Castor, Pollux, and Capella; and all of these presented the same marked planetary appearance, with an absence of scintillation, and altogether different from the ordinary look of these stars. The moon was shining bright—being only two days past the full; the night was cold and frosty, but perfectly calm; the stars resembled the appearance they exhibit in the tropics as described by Humboldt, who says, referring such appearances to atmospheric causes: "thus the more equal mixture of the atmospheric strata in and near the tropics, and that faintness or total absence of scintillation of the fixed stars, when they are 12 or 15 degrees above the horizon, give the vault of heaven a peculiar character of mild effulgence and repose. Cumana and the rainless portion of the Peruvian Coast of the Pacific, were peculiarily suited for such observations; on the average, the fixed stars appear only to scintill te when less than 10 degrees above the horizon, at greater elevations they shed a mild planetary light," &c. And again Humboldt says, quoting another author's remarks, speaking of the climate of Arabia: "the light of the stars is pure, steady, and brilliant; and it is only in the middle of winter that a slight degree of scintilliation is observed." All this, however, is very different from the general look of the starry vault in Canada, where on cold and frosty nights the stars twinkle continually; and where even in summer the planetary look is wanting.

Some stars, however, by an inherent property in their light, twinkle more than others. Humboldt says Vega is perhaps one of the stars which twinkles the least; Arcturus and Capella also

generally shine with a very steady light-my own observations induce to the belief, that, Aldebaran is a star, of the 1st magnitude, which does not shine with as steady a light as those I have named Now with regard to the planetary appearance of the above. stars on this occasion, irradiation cannot be overlooked. It is irradiation which causes a luminous body when projected upon a dark ground to appear of increased size, and the reverse of this holds good, viz. : when a dark object is projected on a bright ground, the light encroaches on the dark body, which consequently appears diminished in size; thus the new moon with the "old moon in her arms," as it is technically expressed, shows this property of irradiation very decisively, in the projection of the luminous portion of the moon's disc, beyond the unilluminated part of the moon. Irradiation causes Venus to appear circular when the planet is in the form of a crescent; I speak in these instances of unassisted vision. The telescope under certain powers overcomes the effects of irradiation, and strips both the stars and the moon of this false light. In a transit of Venus or Mercury across the sun's disc, the true diameters of the planets are diminished by the encroachment of the luminous body of the sun. Irradiation, however, is diminished by the illumination of the ground on which a luminous body is projected. Thus, stars of the 1st magnitude appear to the naked eye of an inferior rank when seen in twilight or by moonlight; and therefore under ordinary conditions, the stars of the 1st and 2nd magnitudes seen by me on the morning of the 13th March, should have exhibited less intensity of light, and presented less appearance of irradiation in consequence of the bright moonlight, than they would have done if seen on a dark night; the reverse, however, was the case, for they not only appeared with planetary discs, (if my vision is to be trusted,) but also shone with greater brilliancy, and with a greater absence of scintillation than ordinarily. To what causes are these appearances to be ascribed ?

It is well known that, when stars are viewed with the best telescopes and with high magnifying powers, they present planetary discs, with alternate dark and bright rings surrounding them, but these discs are spurious, caused it is supposed by the diffraction of light. Viewed with low powers and in the finest instruments, stars of the 1st magnitudes appear as mere points of light; and that they have no sensible discs, is proved by the instantaneous extinction of the light of a star when occulted by the moon. As the night on this occasion was frosty, and the moonlight strong; the stars according to custom should have twinkled more than on a summer night, and as I said before, should have appeared with diminished lustre.

In order to satisfy myself whether I was mistaken in my opinion. I wrote to Mr. Chalmers, F.R.A.S., who resides at Barrie, to ascertain whether he had also seen the appearance I have attemped to describe. His reply corroborates what I have said; and also introduces the subject forming the second part of this paper, viz. the occultation of Spica by the moon, which it was my intention to have observed, but which intention I was unavoidably prevented from carrying into effect. I will now submit to the Institute, that portion of Mr. Chalmer's reply which refers to the subject matter of this paper.

Mr. Chalmers says, "I did observe the planetary appearance of one star of the 1st magnitude as you describe, by mere chance. It was a very cold night, the 12th, (at least here,) but I happened to be up late, and before going to bed I had a look at the moon with the naked eye; I then saw that Spica Virginis would be occulted, and I waited up for it. I extract the notes I made at the time: 13th March, 1-2 a m., mean time, Barrie; Spica Virginis occulted by the moon, the star was actually projected on the moon's disc, as I could distinctly see the edge of our satellite outside the star: the star then disappeared instantaneously, not gradually, but as if it had been extinguished in a moment. The atmosphere was perfectly clear, with a sharp frost; the star did not appear to suffer any diminution of light, and was occulted at the bright edge of the moon ;-curious planetary appearance of the star-telescope used three and a half foot, by Dollond--definition excellent. The occultation of Spica as seen at Barrie, being a subject of far greater interest than my own observations on the night in question, I shall proceed at once to offer to the notice of the Institute, some remarks made by eminent authorities on the way in which stars have been seen either to hang as it were upon the moon's disc, be projected on it, or reappear and disappear along the edge of the moon, in occultations.

Arago saw, during a total eclipse of the moon, a star distinctly adhere to the slightly luminous disc of the moon during the conjunction. Humboldt says, those cases in which it has been asserted that a disappearance and reappearance and then a repeated disappearance, have been observed during an occultation, may probably indicate the ingress to have taken place at a part of the moon's edge, which happened to be deformed by mountain declivities and deep chasms. Lardner says : some observers of sufficient weight and authority to command general confidence, have occasionally witnessed a phenomenon in occultations, which has hitherto been unexplained. According to them it sometimes happens that after the occulted star has passed behind the limb of the moon, it continues to be seen even for a considerable time, notwithstanding the actual interposition of the body of the moon. If this be not an optical illusion, and if the vertical rays come straight to the observer, they must pass through a deep fissure in the moon.

Mr. Hind observes : some authorities adduce an argument in favor of the presence of a lunar atmosphere, from a curious appearance occasionally noticed, when the moon passes before a star-a phenomenon technically known as an occultation-it most frequently happens that the star disappears instantaneously in coming in contact with the moon's limb, and reappears as suddenly and completely, when emerging from behind her disc. But this is not invariably the case; it has been remarked that instead of vanishing entirely at the moment of contact, the star is sometimes seen projected on the moon's disc, for several seconds of time, and a similar appearance takes place, (though more rarely,) before the final emerging from the other limb. About twenty years ago, a good deal of interest was excited amongst astronomers in reference to this matter, and some occultations of the bright star Aldebaran, were closely watched at the principal European observatories. The result proved far from conclusive-at the royal observatory, Greenwich, some observers saw nothing unusual either at the immersion or emersion of Aldebaran, the star disappeared and reappeared instantaneously; others on the contrary, saw it distinctly projected on the moon's disc for a second or two, before being occulted, and these persons even observed with similar instruments, and from the same station.

Instances are on record where a star instead of disappearing finally, when first in contact with the moon's limb, has run along it and reappeared several times, evidently between the mountains on the edge of her disc. On the 7th March, 1794, Professor Koch, saw Aldebaran disappear and reappear three times, about thirty seconds or so intervening between immersion and emersion. Another observation of a similar kind was made by Mr. Rumker, at Hamburg, on the 19th February, 1820; a star of 7th magnitude appeared to run with extreme rapidity along the summits of the mountains in the moon's edge, by which it was eclipsed from time to time. This "magnificient spectacle" continued nearly ten minutes, when the star finally vanished. The above remarks by very eminent observers, fully bear out the occurrence of such phenomena as recorded at Barrie, on the evening in question. To account satisfactorily for all such appearances is another matter. Mr. Hind seems disposed to refer the differences which so many practised observers have exhibited, with regard to the occultation of Aldebaran, to the instruments employed, and to the observers themselves, for a satisfactory explanation of the whole.

The question to be decided on the present occasion, is whether it is probable that the projection of Spica upon the moon's limb, as described by the observer at Barrie, is in any way connected with atmospheric or optical causes, which may have influenced the peculiar appearance of the stars on that night, or rather morning—or whether it is to be ascribed to a lunar atmosphere, to an optical illusion, or to some other cause. On these points I do not presume to offer an opinion; but leave them for the consideration of the members of the Institute, some of whom may be able to give a more satisfactory reply than I can. In conclusion I may observe that this paper contains but a moderate amount of original matter, but if the subject is one deserving attention, the quotations from authors of repute are necessarily frequent and unavoidable for its due consideration.

# REVIEWS.

Recherches sur les principes Mathématiques de la Théorie des Richesses, par Augustin Cournot, Recteur de l'Académie et Professeur de la Faculté des Sciences de Grenoble. Paris : Hachette, 1838.

"Whatever is obscure is not French," said Voltaire in allusion to the French language. Since Voltaire's day, the remark may be extended to many other developments of French intellect besides their language. In matters of pure science, whether inductive or analytical, the French justly rank foremost of the age since Newton died, but most especially do they surpass all other nations in the precision and clearness of style with which their writers are in the habit, seemingly instinctive, of presenting their subject for discussion; and in dissecting the most recondite and intricate phenomena, they handle the scalpel with an easy grace which *nos autres* are fain to admire but try to imitate in vain : whatever objections we may

make to the principles, the method, or the conclusions of a French philosopher, we may always be sure that it is our own fault if these objections are founded on a misconception of his meaning. To the French philosophers we owe almost entirely those applications of abstract science to the problems of social organisation, which are already beginning to produce important results: the calculus of probabilities, as given by Laplace, is destined to effect perhaps the greatest social changes that the world has yet seen: still, in that very wide field of research, which we call by the general name of political economy, no mathematician had hitherto ventured to intrude; yet surely no science ever called louder for this aid. Search where we will amid the labyrinth of words which at present is said to constitute our political philosophy, we shall not fail to come across definitions undefined, many-headed ambiguities of terms, confusions of consequence and hypothesis, hardy prognostications of contingencies that never happen, till the exasperated searcher resigns in despair the "talking theory," and submits, sulkily enough, to the "silent practice."

It may fairly be doubted whether our science of political economy has made one real step in advance since the famous treatise of Adam Smith; yet, admirable in itself and wonderful considering the circumstances of its production, as this treatise is, Smith has done little more than clear away obstructions and trace out the foundations of the building which is to be: materials enough were ready at hand, but tools were wanting. As in most other sciences, the first investigators are stopped by failure of modes of expression and forms of calculation; seldom has it happened that a science springs all-armed from the brain of one man as of Newton; yet if Archimedes had possessed the Arabic numerals and the Hindoo algebra, the world would not have waited two thousand years for a Newton; and if Adam Smith had possessed the calculus, we should not at this day be wearied and perplexed with the prolix circumlocution of Ricard, or the refining complications of Mill.

The work cited at the head of this article is the first attempt that we are aware of to submit any part of this subject to formal analysis. Its author is a well known and able French mathematician, and his work is no less remarkable for the novelty of its method and the lucidity of its style, than for the nature of the results which he has obtained, and for which he justly claims the character of scientific deductions. We do not propose in this place to examine the truth of the principles from which he sets out : all that we contend for is that, granting the principles, the conclusions follow inevitably. As the
work has never been translated into English, so far as we are aware, our object will merely be at present to give an outline of the system followed and some of the deduced consequences, paraphrasing, as nearly as may be, the statements of the author himself, and for this purpose we shall let him introduce the "theory of riches," in his own words :

One cannot conceive that men can live any length of time in convection with one another, without practising the exchange of property or services, but there is a wide step between this natural, and, so to speak, instinctive act, and the abstract idea of a value of exchange which supposes that the objects to which we assign such a value are dans le commerce; that is to say, that we are always able to exchange them for objects of equal value. However, the things to which the condition of commercial relations and civil institutions permit us thus to assign such a value are those which in actual language, we commonly design by the word "riches;" and for the purposes of our theory, we shall identify absolutely the meaning of the word "riches" with that presented by the words "exchangeable values" \* We must distinguish well between the abstract idea of "riches" or "exchangeable values," (an idea fixed, and in consequence capable of lending itself to rigorous combinations,) from the accessory ideas of utility, rarity, adaptation to the wants or enjoyments of man, which the term "riches" in ordinary language recalls; these ideas are by nature variable and indeterminate, and no scientific theory can be founded on them. The division of economists into sects, and the war carried on between practical men and theorists, arise in great part only from the ambiguity of the word "riches" in common language, and the confusion which has always prevailed between the fixed, determinate, idea of "exchangeable value," and those of "utility" which every one can estimate in his own fashion, because there is no fixed standard of measure to which reference is possible. \*

We must also distinguish between the *relative* changes of value, which are exhibited by the variation of the relative values, from the *absolute* changes of value of one or other of the commodities between which exchange has established relations.  $\pi$  \* In our theory, there exist only *relative* values: to seek for others is to contradict the notion itself of "exchangeable value," which implies necessarily that of a relation between two terms. Moreover, the change effected in such a relation is a relative effect which can and ought to be explained by absolute changes in the terms of this relation. There are no such things as absolute values, but there are certainly absolute movements of rise and fall in values, and the knowledge of the laws which regulate these constitutes the "theory of riches."

Having thus precisely defined the object of his researches, Cournot devotes a chapter or two to the consideration of "money," and establishes some curious relations among the "rates of exchange" of different markets, but we must pass on to where, in search of the principles which shall govern his investigations, he clears his way by an onslaught, too well deserved, on his predecessors in this region. He says : To lay the foundations of the theory of exchangeable values, we shall not, with the majority of speculative writers, remount to the cradle of the human race; we shall not take in hand to explain either the origin of property, or that of the exchange or division of labour. This all belongs without doubt to the history of man, but has no influence on a theory which can only become applicable at a very advanced stage of civilisation, a stage when (to use the language of geometers) the effect of the *initial circumstances* has entirely ceased.

We shall appeal to but one axiom, or, if you please, we shall employ one hypothesis alone, namely, that every one tries to get for his property or labour the greatest possible value. But in deducing the logical consequences of this principle, we shall attempt to fix, better than has yet been done, the elements or data which observation alone can furnish. Unhappily this fundamental point is that which theorists almost unanimously present to view in a manner, we will not say, false, but-absolutely meaningless. "The price of things," say they, with almost one voice, "varies directly as the demand, and inversely as the supply."

Our author then proceeds to shew, that, taken in its strict mathematical meaning, the principle is palpably wrong, but as we do not imagine that the writers who use it, ever meant it to bear such meaning, it is not necessary to follow him here: doubtless, the "variation" spoken of is only a loose way of expressing increase and decrease, without specifying that particular mode which is implied in the technical word "variation." The following is of more importance:

Besides, what are we to understand by the "demand?" It is without doubt not the quantity which is really sold at the demand of buyers, for in that case there would result from the pretended principle the consequence, which is in general absurd, that the dearer a commodity is, the more of it there will be sold. If by "demand," we are to understand only a vague desire to possess the commodity, abstraction being made of the limit of price which each demander implies in his demand, there is scarcely a commodity for which we might not consider the demand as infinite; and if we are to take count of the price at which each demander consents to buy, each provider consents to sell, what means the pretended principle? It is, we repeat, a proposition—not erroneous, but-devoid of meaning; and accordingly, all those who have agreed to announce it, have equally agreed not to make any use of it. Let us try to betake ourselves to principles less barren.

We must here condense somewhat. The law of the demand, that is, the relation between the price of a commodity and its sale, (for Cournot justly uses "sale" and "demand" as synonymous, no theory being able to take count of a "demand" not followed by a "sale") is altogether unknown, nor is it likely that experience could furnish data, or analysis supply a formula which should determine and represent it, depending as it does on circumstances so numerous and variable and often of so shadowy a character as to elude the subtlest grasp. All we know of it is, that *in general* the sale or demand of a commodity increases

when the price decreases, and vice versa : the qualification "in general" being here introduced to exclude certain classes of commodities, such for instance as articles of curiosity and vertu, where a considerable fall in the price might even annihilate the demand altogether: if diamonds could be manufactured as cheaply as glass, no one would buy a diamond ring. Such cases, however, may be neglected in the general theory. The rate of this increase or decrease of the sale, in consequence of the fall or rise of the price, is dependent on the particular commodity, and may be more or less rapid; in most manufactured products, the increase of sale would be more than doubled if the price were to fall one half: in other cases, such as the necessaries of life, fuel, bread, and the like, and in cases where the demand is a necessity to a limited class of consumers, as in workmen's tools, weapons of war, philosophical instruments, there might be a considerable fall in price without the demand being much affected at the time. Although this law of the demand is thus unknown, we are not thereby precluded from reasoning with regard to it, for by well known processes of analysis, properties of a function may be discovered when the function itself is undetermined. If we now consider the gross produce of any particular commodity, that is, the quantity sold multiplied by the price at which it is sold, it is clear that the value of this produce may be made as small as we please by diminishing the price sufficiently, for even if the commodity were given away, the consumption would still be a limited quantity. On the other hand, we can conceive a price so high as to put an end to the sale altogether, so that this gross produce would again vanish: between these two points therefore, there must be some particular price at which this same gross produce will have attained its greatest value possible; up to which point it has been increasing and afterwards begins to diminish-in technical language, it admits of a maximum value. This then is the one great lever with which Cournot is going to move the world of economics, and we shall now proceed very briefly to indicate the manner in which he has used it. Clearly, however, we are not able to plunge at once into the thick of the market, and demand that the principle shall be applied immediately to the first commodity we lay hold of ; many circumstances must be first considered, and it will be wiser to begin with the simplest case we can conceive, even if it be a wholly imaginary one, and then proceed step by step till we arrive at a stage which may be approximately level with the actual condition of things as we see them around us. Not the least part of the merit of Cournot's treatise consists in his admirably-graduated progress from the simple to the complicated.

•

the imaginary to the real. Setting out then with the case of an absolute monopoly, where the production of a commodity is entirely in the hands of a single person, the price will be determined by the principle that the net produce of the commodity shall be a maximum; by the net produce meaning the revenue obtained by the sale, less the cost of production. If the cost of production increase, the price will also be increased, though not necessarily to the same extent, and if this increase of cost be not supported by the producer, but by the consumers or by the agents who convey to the consumers and are reimbursed by them, the commodity will always be enhanced to the consumer, and the net revenue of the producer will be diminished, yet the price paid to the producer may rise or fall according to the varying circumstances of the case. An important distinction here developes itself according as an increase of production is attended by an increase or decrease of the cost of production. In the majority of cases of manufactures the latter state will prevail; for, the larger the establishment, the less in proportion are its expenses. In the products of agriculture and in the working of mines, the contrary may often happen, and even in cases which at first sight have something parodoxical about them; for instance, it is said that the Times newspaper has reached such a circulation, that every extension of it diminishes the profits of the proprietors, the actual cost of production of each copy of the paper being less than the price charged for it, and the space devoted to the advertisements, from which the profits are derived, being filled to its utmost extent. Another curious class of cases falls between the above two, namely, those where the cost of production is unaffected, either by the increase or decrease of the production, and the price is consequently the same as if the commodity were produced without cost. For example, the expenses of a bridge which is supported by toll will be sensibly the same whether the passers over are few or many, and of a theatrical performance, whether the boxes are full or empty.

In all this investigation it has been supposed that there is nothing to prevent the producer from producing the amount which is required to give him his *maximum* revenue, nor on the other hand from lowering his price to that required for the same *maximum*. If otherwise, a totally different calculation is called for, which we need not here enter into.

Closely connected with the foregoing, is the theory of taxation, which may be considered as an artificial increase of the cost of production. We need only consider two sorts of taxes, the *direct* and the *indirect*. The former levied on the net revenue of the producer, whether fixed or sliding, has no effect on the price of the commodity, nor on the quantity produced; neither does it in any way fall on the consumer. Not the less may it be prejudicial to the general welfare : the following remarks of our author are exhaustive :

"This tax, though it does not reach the consumer, may be nevertheless very hurtful to the public interest: not mainly because in restricting the wealth of the producer so taxed, it restrains his means of consumption, and so influences the law of the demand of other commodities, but especially because the portion taken away by the tax on the producer's revenue is commonly used in a way less profitable to the increase of the annual production of the national wealth, and of the well-being of the people, than if it had remained at the disposal of the producer himself. We shall not here examine the effects of this abstraction on the distribution of products, whether natural or manufactured, though doubtless this is the ultimate object of the problems connected with the theory of riches, but we may remark, in harmony with all the authorities, that the tax on the producer's revenue, even if it does not hinder the productive funds from producing as much as they did before the tax was imposed, is an obstacle to the creation of new funds for production, and even, where the tax is a sliding one proportional to the revenue, to the improvement of the existing funds. No one will employ his capital in the creation of new funds for production, or in the improvement of those existing, if, by reason of the tax with which he finds the net return of his capital affected, he no longer obtains the ordinary interest accruing from capitals employed in undertaking; of the same kind. It is by closing the openings for employment of labour and industry that such a tax, when excessive, acts in the manner the most disastrous."

Of indirect taxes, we may distinguish the two kinds known as specific and ad valorem. In the former case, the loss sustained by the producer exceeds of itself the gross profit to the treasury, leaving the loss sustained by the consumers wholly uncompensated. Under this head may also be classed the system of *bounties* or *premiums*, the result being that the gain to the producer which is effected by the bounty, is essentially less than the sacrifice caused by the fall in price produced thereby. With regard to ad valorem duties, Cournot establishes a very beautiful and simple formula,\* by which a duty of this kind is shewn to be equivalent to a certain increase in the cost of production or transmission of the commodity. Hence such a duty falls the heavier, according as the cost of production is greater. Just as in the specific duties, the loss sustained by the producer is greater than the income of the treasury, and that by the consumers is wholly uncompensated.

<sup>\*</sup>If the tax on each unit of the commodity be to its price in the ratio of n to 1, the effect will be the same as if the cost of production were increased in the ratio of  $(1-n_i)$  to 1, Thus if the tax were 12 per cent., the increase of cost which would be equivalent to it would be about  $13\frac{1}{2}$  per cent.

From the case of an absolute monopoly in the hands of a single proprietor, we pass to that where two independent proprietors are supplying the same market. Each of these will endeavour to render his own net/revenue the greatest possible. If the two proprietors are in precisely similar circumstances, so that the sale by each is the same, then follows the curious result that the revenue derived according to the foregoing principle is less than that which would have been derived if the two sources had been united into one, or if the two had entered into partnership.

"How happens it then that producers, for lack of understanding, fail to stop, as in the case of monopoly or partnership, at the price which in effect gives them the greatest revenue? The reason is, that if one producer had fixed his production in accordance with such a condition, the other might with a momentary benefit carry *his* production to a higher or lower level: certainly, he would soon be punished for his mistake, because he would force the first to adopt a new level of production which would in return re-act unfavourably upon himself. But these successive reactions, far from bringing the two back to their original state, will make them deviate more and more widely from it. In other words, the state supposed will not be one of *stable equilibrium*; and although the most favourable for the producers, it will not be able to exist except by a formal compact between them, because we cannot suppose in the moral world men exempt from mistakes and inconsiderateness, any more than in physical nature we find bodies perfectly rigid, points of support absolutely fixed, and the like."

The same reasoning holds when the number of independent producers is more than two; the effect of the competition in all cases being to lower the price, a result which indeed we might well have asserted a priori, but which has here for the first time received from our author its logical exposition as a scientific fact. The most important, and the most common of this class of cases, is where the concurrence of producers is so great, that any partial production might be cut off without sensibly affecting the whole production or the price of the commodity : here then the effect of monopoly is entirely extinguished, and the benefits of this are are not less felt by the public than by our mathematician, whose calculus is wonderfully simplified in consequence. The same principle still governs the price; an increase in the cost of production, including the case of a specific duty, always raises the price, but to an extent which is in all cases less than the increase of cost; and any additional expenses incurred by the commodity after it has left the hands of the producers will lessen the price obtained by them. The loss sustained by the producers, by reason of the imposition of a specific duty, is less, while that sustained by the consumers is of itself greater, than the produce of the tax. Duties ad valorem follow precisely the same rule as in the case of a monopoly.

Hitherto, we have considered the commodity discussed to be a simple one—that is—one in which only one class of producers has been concerned: commodities of this kind do not, however, form the majority of ordinary products: we cannot do better than let Cournot himself speak, in introducing this important distinction:

"Very few substances are consumed in the state in which they issue from the hands of their first producer: generally one and the same substance enters into the composition of many different products that are more directly appropriated to consumption; and reciprocally, many primitive substances concur in the formation of each of these products. It is clear that each producer of primitive substances, ought to try to make the most of his property; and then we ought to investigate according to what laws are divided, among the different producers, the profits which they together make by virtue of the law of consumption of the ultimate products. This short *exposé* will be enough to render intelligible what we understand by the effect of the *concours* of producers of different commodities, an effect which must not be confounded with that of the *concurrence* of producers of the same commodity, which has already been discussed."

In fact, we arrive at a result precisely the opposite in this case of what we had in the former. The effect of competition among concurrent producers of the same commodity, was to lower the price: here the effect is to raise the price, and the division of proprietaries acts disadvantageously, not only for themselves, but the public ; this disadvantage also being increased in proportion as the number of primitive substances concerned in the production of the compound commodity is greater. When an increase takes place in the cost of pr duction of one of the primitive substances, or when a tax is imposed on it, the price of this one and of the compound commodity will be raised, and at the same time the prices of the other concurrent substances will be lowered, but the rise of price will be less than the assumed increase of cost or the tax. If a tax be imposed on the compound commodity, it will cause the price of each of its components to fall, while that of the commodity itself will be raised, but to an amount which is less than the tax. These results are of a very remarkable character, and, though established by a somewhat intricate calculus, there seems no reason to deny them the character which our author claims for them of possessing all the certainty of mathematical theorems.

The remaining portion of the work under review, is taken up with an examination of the sources from which the wealth of each nation is derived, and the effect produced thereon by the communication of markets. Our limits do not permit us to follow him through these investigations, and indeed, this part of his work is to us the least satisfactory of the whole. The analysis employed is not powerful VOL. II. --N enough for the work, and our author is compelled to descend from his vantage-ground of rigorous scientific research, and enter into contest with the "ecrivains economiques," in that very arena of wordiness for which he has so justly reproached them. In some places also his reasoning may with justice be impugned, and we have therefore less computction at cutting short our abstract. Enough has been said to give our readers an idea of the nature of this admirable treatise, and of the style of research pursued, and results obtained in it: we think it may truly be regarded as the first attempt. and a successful one, at founding a true science of wealth on the only base of observation and induction : we must, however, not forget, that the "theory of riches" is only one portion of the social economic field : the true weal of a nation depends, not merely on its wealth but infinitely more, on the mode in which that wealth is distributed, and the investigation of the "how and why" for this case must be the ultimate aim of all the problems of civil polity : we would recommend to the attention of our readers, the following eloquent and consoling remarks, with which Cournot closes his book:

We must remember that questions such as these, are not resolved by the argumentations of doctors, nor even by the wisdom of statesmen. A superior power forces nations into this or the other, track, and when a system has had its day, sound reasoning will be as unavailing as sophistry, to restore to it the life it has lost. The craft of the statesman consists then in moderating the ardour of the spirit of innovation, without trying to maintain an impossible struggle against the laws of Providence. The possession of a sound theory can aid this labour of resistance to abrupt changes, and helps in facilitating the transition from one regime to another; by bringing more lights to the point in dispute, it extinguishes the passions that are in combat. Systems have their fanatics; science, which succeeds to systems, never has. Lastly, if the theories connected with the organisation of society, do not rule contemporaneous facts, they at least render plain the history of facts accomplished. We may up to a certain point, compare the influence of theories of polity on society with that of theories of grammar on language. Languages are formed without the consent of grammarians, and are corrupted in spite of them; but the labours of these bring day-light to the laws of formation and decay of languages; their rules hasten the period at which a language reaches its perfection, and retard somewhat the invasion of the barbarism and bad taste which corrupt it."

J. B. C.

Account of the U. S. Naval Astronomical Expedition to the Southern Hemisphere, during the years 1849,-50,-51,-52; compiled by Lieut. Gilliss, U.S.N., Superintendent of the Expedition. Washington, 1855: 2 vols, quarto.

The Expedition of which the work above named gives a description, was determined on by an act of Congress, in 1848, for the purpose chiefly of enlarging and correcting the catalogue of stars for the southern hemisphere. The station selected for the requisite observations, was Santiago, the capital of Chile, which from its geographical position, and the purity of its atmosphere, was admirably adapted for effecting the proposed objects. Lieut. Giliss was directed, in addition to his astronomical labors, to collect materials for the advancement of the sciences of magnetism and meteorology, together with information, relative to the natural history, the topography, and the political, social and commercial condition of Chili, and the contiguous countries.

It is with such miscellaneous matter that these volumes are principally filled; a brief description only of the astronomical work is given at the end of the first volume; but the astronomical results will appear in additional volumes not yet published. The first volume prepared by the Superintendent, relates chiefly to the countries on the western side of South America. The second volume contains a narrative of two journeys across the Andes and Pampas, made by Lieut. MacRae, U.S.N., the chief assistant, together with some beautifully executed engravings of the specimens of natural history, mineralogy, and Indian antiquities, collected by the officers of the expedition, and accompanied by notices drawn up by scientific men in the United States, eminent in their respective departments.

The writers appear to have spared no pains in collecting materials for their work; and while due regard has been paid to arrangement, they have succeeded in putting them together in a very pleasing and spirited style. As a book of travels, apart from its scientific character, it deserves certainly to occupy a very high rank.

The nature and extent of the labors in which the officers of the expedition were engaged, may be learned from the brief account given by Lieut. Gilliss, at the close of the first volume :----

During the summer and autumn months succeeding our arrival, there was almost uninterrupted fine weather. From the 10th of December, when the equatoreal was ready for use, night followed night unrivalled in serenity; and to the close of the first series of observations on the planet Mars, Jany., 81, there were but four unsuited to work. Labour so continuous in a climate as dry almost as an oven, told severely on unacclimated constitutions; and it was soon perceived that the principal assistant must be temporarily released, or be broken down, perhaps permanently. The opportunity to send him to Valparaiso for the meridian circle, was therefore a welcome one. Messrs. Hunter and Smith, recorded for me on alternate nights, until the former was disabled by being thrown from a horse. All the aid was then from Mr. Smith; besides which duty, he became wholly charged with the meteorological observations for every third hour, between six, a. m., and midnight. Within the forty-eight working nights embraced between the above dates, nearly 1400 observations of the planet were accumulated; and by the time that this series terminated, the piers for the meridian circle were finally completed, the health of Lieut. MacRae re-established, and we were able to give undivided attention to its erection and adjustment; so that the instrument was ready for use about the middle of February.

But it must not be inferred that our nights from the 31st of January, were passed idly. Observations for approximate place of the circle had commenced some days before, and extra hours of every night were spent in becoming familiar with the details of the superb instrument that Messrs. Pistor and Martins had sent us from Berlin; and thus, by the time its adjustments were perfected, both of us were expert in its manipulation. Beginning within 5° of the south pole, a systematic sweep of the heavens was then commenced in zones or belts. 24' wide. Working steadily towards the zenith on successive nights, until compelled to return below again to connect in right ascension, the place of every celestial body that passed across the field of the telescope, to stars of the tenth magnitude, was carefully noted down. The space immediately surrounding the south pole, was swept in one belt of 5° by moving the circle, and each zone overlaps those adjoining both in right ascension and declination. Above the polar belt there are forty-eight others, making in all 24 12' of declination, within which we obtained 33,600 observations of some 23,000 stars, more than 20,000 of them never previously tabulated.

From Oct. 1850, Messrs. MacRae and Phillip had the entire charge of the instrument for zone observations. When an accident to one of the screws compelled the services of both at the same time, until a new one was received from Berlin, I devoted every other night to the examination of the stars in the catalogue of Lacaille, and between the zenith and our upper zone, which had never been reobserved. \* \* \* \* As may be supposed, the discrepancies

between our estimations of the magnitudes of stars, and those of preceding observers were very considerable in a multitude of cases; but we endeavoured to preserve an uniform system, and will reconcile discordances if we can. There were many errors in Lacaille's work, at the Cape of Good Hope, and quite a number of his stars do not exist in the reduced places of the British Association publication; but we were only amazed that he should have been enabled to accomplish so much, and so well, with a telescope only half an inch in diameter, and in the brief space of ten months.

It was a great satisfaction to work with an instrument like ours, but there was almost too much of it. Out of 132 consecutive nights, after the equatoreal was mounted, there were only seven cloudy ones! Of necessity, to afford so large a proportion, the air must be exceedingly destitute of moisture, a condition of things favorable to telescopic vision, but not so to eyes employed during prolonged observations. Much as the expedition succeeded in effecting, the continuous labor of mind and body occasioned by the nature of the work, and the limited number of assistants, together with the trying influences of climate, seem seriously to have interfered with its complete success. Lieut. Gilliss writes:

We were on the further extremity of the continent, and so distant that the words of my earnest appeal for help, grew cold before they reached home; unmistakeably convincing me before the close of the first autumn, that one of the objects of the expedition could only be partially accomplished. I had hoped the day was not distant, when astronomers would say, the American Navy has mapped the whole heavens. The observatory at Washington, had commenced a catalogue, intended to embrace all the stars that appear at a sufficient height above its horizon. With sufficient force we could easily have tabulated the remainder, and the noble work would have been a monument to the service for all time. But it was not to be. There is a limit to physical exertion under every elime, and we were not less human than our kind. I had only half the requisite number of assistants for an undertaking so laborious; and, fixing that limit at the utmost bound consonant with the preservation of health and vision, when my own time was occupied in observations of Mars or Venus, until the meridian circle was again in complete order, it was necessarily unused on alternate nights.

But if the success of the expedition was not in every respect commensurate with the ardent aspirations of it zealous and able superintendent, there is one collateral result which will be hailed with satisfaction by all friends of science—the establishment of a national observatory at Santiago. Mr. Gilliss goes on to say :

We had scarcely organized work systematically, before it was intimated to me, from the university, that the government (of Chile,) would probably establish an observatory at our departure, and to this end was desirous to have one of the professors of mathematics, and two of the most advanced and promising students of the National Institute, acquire a knowledge of the instruments. The utility of such an establishment, and the honor it would reflect on the country, had been urged by the Chilean Ambassador at Washington, prior to our departure from the United States; and it was a source of no little gratification to me, to witness the incipient step promptly taken towards the realization of an object so noble.

Throughout nearly the three years of our residence at Santiago, the government evinced the most earnest disposition to forward the objects of the expedition, and to extend every possible consideration to its members, officially and personally. To its liberal and enlightened policy on all questions of science, literature, or art, the world is indebted for more than one valuable contribution; its schools of arts, music, painting, and botany, the elaborate work on its natural and political history, and its geological topographical survey, are all evidences of its generous patronage. The culminating step was yet to be taken; and there was a time when we had looked forward to this—the establishment of a national observatory at our departure, with something approaching to certainty. \* \* \* Learning that my observations would cease about the middle of September, Professor Domeyko, then rector of the National Institute, was authorized to say

## REVIEWS-U. S. NAVAL ASTRONOMICAL

that the government would be glad to purchase our observatories as they stood. Dr. Charles Moesta, a graduate of the university of Marburg, was appointed director, and was placed in communication with me, so that he could become familiar with his instruments by the time we were ready to surrender them.

On the return to the United States, of the rest of the expedition by the Panama route, Lieut. MacRae was despatched home via Buenos Ayres, across the Andes and Pampas. The chief objects of this journey, were to determine the variation of magnetic intensity dependent on the distance from the earth's centre, to assist Baron Lindenau in his investigations relative to atmospheric refraction, and to collect general information respecting the geography and meteorology of the Andes and Pampas.

The entire journey occupied him about sixty days, of which twelve were employed in observations within the Andes. Accidents having unfortunately occurred to the chronometers, by which discredit might be thrown on the longitudes of his stations, Lieut. MacRae, on his arrival in the United States, volunteered to retrace his steps at his own cost if a new set of instruments were supplied to him. His offer being accepted, he embarked for Buenos Ayres, in August. 1853, crossed the Pampas and Andes to Valparaiso, and finally returned to the United States in March, 1854.

Reports of both his journeys are given in the second volume, occupying some eighty pages. With respect to his magnetic observations, to which he alludes very briefly, he remarks that he encountered much difficulty in making accurate observations in mountain passes, on account chiefly of local attraction and strong winds; he however. considers their accuracy sufficient to justify the deduction that the intensity diminishes with elevation, by some law as yet unknown.

But to return to the 1st volume. This, the exclusive work of Mr. Gilliss, is the more acceptable, from the fact that previous books, or most of them, respecting Chili, refer to a condition prior to the last quarter of a century, and describes what Chili was, instead of what it is.

In the opening chapter on descriptive geography, and in the following one, on the distribution of industrial resources, the author enters into various details relative to the physical and social causes which have operated in determining the position of the cities, the comparative progress of different districts, and their capacity for further improvement.

In the chapter on earthquakes, we read some vivid descriptions of

these terrific visitations, some derived from national records, others witnessed by the author himself.

Of the former class is the celebrated earthquake of 1835. The description refers chiefly to Concepcion and Talcahuano.

At forty minutes past eleven o'clock, the tremor commenced without noise, its violence gradually increasing during the first half minute, yet not so much as to cause general alarm. Meanwhile the rumble was heard, and at the end of that time, the convulsive motion became so strong, that the whole population field to open places for safety. Before a minute had elapsed, the awful motion so increased, that people could scarcely stand; and in thirty seconds more, an overpowering shock caused universal destruction. Concepcion was a fourth time in ruins—its people shrieking under the agony of terror and bodily injury; the very ground on which they were prostrated gaping wide with every throb, and the atmosphere almost irrespirable with dust. From the first tremor to the termination of the great shock was two and a half minutes, during the longer portion of which time, none were able to stand unsupported; even animals spreading out their legs to avoid overthrow, and birds taking to the wing.

Simultaneously with the beginning of the convulsion, the water rose about a foot in the river at Concepcion, and in the bay of Talcahuano, without first retiring, swelled up to high-water mark; but the great sea-waves came not for a long time afterward.

An hour and ten minutes had elapsed from the destruction of the town of Talcahuano, which was also destroyed, when,

The sea retired nearly a mile, leaving in the mud vessels that had anchored in from four to six fathoms water. A few minutes after, the first great wave approached in an unbroken wall of water, thirty feet high between the island of Quiriquina, and the western shore of the bay. It broke over everything within that distance of tide level; dashed the ships along like boats; bore one from the stocks where it was nearly ready for launching 200 yards inland; removed 24-pounder cannon some yards and overturned them; and finally, rushed back with such a torrent that everything moveable not buried under the ruins was carried out to sea. The inhabitants occupied the heights at the back of the town, not less appalled at this display of resistless power than despondent at the ruin it caused them. Ships were again left aground in the bay, until half-past 1, p. m., (i. e. after an interval of one hour,) at which time a second wave was seen rolling through the same channel, with more impetuosity than the first, whirling them about each other as they floated, and was only less destructive in its effects, because there was less to destroy. Twenty minutes later, a third came onward. But this was crested-foaming like the breakers across a dangerous bar during a storm; and as it swept tumultuously along the shores, bearing everything irresistibly before it, the roaring noise was horrible. Quickly retiring, the sea was seen covered with wrecks of houses, furniture, and goods of every character, from the shattered magazines. Apparent exhaustion followed these efforts, for there were no more great waves, though for some hours the sea rose and fell two or three times each hour, and both earth and water trembled.

## 200 REVIEWS-EXPEDITION TO SOUTHERN HEMISPHERE.

Several days elapsed before the tide rose to within five feet of the usual marks; and as late as the middle of April, there was still a difference of two feet, indicating an elevation of the coast to that amount—a fact substantiated by beds of dead muscles and limpets. At the same time the island of Santa Maria, 40 miles distant in a S.W., direction, and the southern shore of the neighboring bay of Arauco, were more affected. The former was upheaved an average of nine feet, its north end having been raised two feet more than the south point, whilst the main land S.E., of it was only left six feet above its previous height.

At the same time of the ruin, and until after the great waves ceased, the water in the bay was quite black, and from the bubbles of air, or gas that escaped was apparently boiling in every direction. It also exhaled a sulphurous smell, and destroyed shoals of fish, whose dead carcases added to the variety of floating objects. Whilst the waves were coming in, two explosions were seen, one a column of dark smoke, like a tower outside the Island of Quiriquina; the other resembled a huge jet of aqueous vapor, thrown up in the bay of San Vincente, which is separated from that of Tulcahuano by a narrow isthmus. At the disappearance of the latter, a whirlpool marked the spot, as though a cavity had been opened into which the sea was pouring. At one place in Talcahuano, and several near Concepcion, the ground swelled like large bubbles, and then bursting, discharged quantities of black and fetid water.

After describing some examples experienced by himself, he enters somewhat into the theory of earthquakes, and relates a fact showing the extent of a region simultaneously affected by the same shock. By means of the electric telegraph erected between Santiago and Valparaiso, it was ascertained that these two cities 64 miles apart, had been shaken precisely at the same instant.

Space does not remain to analyse or comment on the able and lucid remarks of the author on the government of Chile, the condition of its society, and the practices of its church; nor can we do more than call the attention of his readers, to the lively narrative of his visits to various districts in which many similar remarks are embodied. We shall be content to terminate this short notice by quoting from the concluding paragraph of the book, where the writer in language, we think, that speaks well both for head and heart, deprecates the charge to which too many travellers have justly exposed themselves : that namely of abusing the hospitality of their hosts, by betraying their defects. He writes :

Many things may have been told in the preceding pages, apparently ungracious from one who acknowledges so many attentions, so many acts of courtesy, and such valuable assi-tance; but I claim justification and pardon. These very acts would have inspired lasting regard for the people, even had not nature invested their country with elements to create thee strongest interest in its, and their welfare. And first, it is more than difficult for a foreigner to comprehend fully, or to appreciate properly the customs and motives for thought and action, of the nation in whose midst he tarries. He brings the standards of his own land by which to measure them; and though long residence may soften the home character of his criticism, the impressions of childhood will not be effaced, but like magic ink will appear plainly whenever subjected to certain ordeals. Constant occupation prevented much of the intercourse that would have imparted some of these softening influences; and it may be that I continue scarcely more competent to truly estimate Chile and Chilenos than in 1849. Faithfully, however, has the motto been kept before me "nothing extenuate, nor ought set down in malice." More than this: next to my own, there is neither land nor people for whose prosperity and happiness I feel such earnest desire; none whose advancement I would make such efforts to promote. Will these sentiments give me a right to indicate faults; notas a censor regardless of the pain he inflicts, but as the friend who details errors that they may be the better corrected; the admirer who desires to perfect the object of his esteem? On these grounds I ask the indulgence of friends in Chile praying they will ever believe me grateful for their untiring kindness and hospitality.

G. T. K.

# The Testimony of the Rocks: By Hugh Miller. Boston: Gould and Lincoln, 1857.

Hugh Miller's melancholy end has naturally stamped upon this work an interest of no ordinary kind. But apart from the adventitious interest with which it is thus surrounded, the intrinsic merit of the work itself, the grandeur of its theme, and its fresh and vigorous thought, garbed in the same picturesque word-painting as of old, may fairly claim for it a high place in the consideration of the thinking world. The "Testimony of the Rocks" consists of a series of lectures having for their primary argument the high antiquity of the globe, in opposition to that narrow view which the great Chalmers declared to be unsupported by the Mosaic Record, and which has long been virtually abandoned by many of our most eminent divines—amongst others, by the present venerable head of the Anglican Church itself To use our author's words—

It is now exactly fifty years since a clergyman of the Scottish Church, engaged in lecturing at St. Andrews, took occasion in enumerating the various earths of the chemist, to allude to the science, then in its infancy, that specially deals with the rocks and soils which these earths compose. "There is a prejudice," he remarked, " against the speculations of the geologist, which I am anxious to remove. It has been said that they nuture infidel propensities. It has been alleged that geology by referring the origin of the globe to a higher antiquity than is assigned to it by the writings of Moses, undermines our faith in the inspiration of the Bible, and in all the animating prospects of the immortality which it unfolds. This is a false alarm. The writings of Moses do not fix the antiquity of the globe."

' The bold lecturer on this occasion,-for it needed no small courage in a divine of

#### REVIEWS-THE TESTIMONY OF THE ROCKS.

any Established Church to take up, at the beginning of the present century, a position so determined on the geologic side,-was at the time an obscure young man, characterized, in the small circle in which he moved, by the ardor of his temperament and the breadth and originality of his views; but not yet distinguished in the science or literature of his country, and of comparatively little weight in the theological field. He was marked, too, by what his soberer acquaintance deemed eccentricities of thought and conduct. When the opposite view was all but universal, he held and taught that free trade would be not only a general benefit to the people of this country, but would inflict permanent injury on no one class or portion of them; and further, at a time when the streets and lanes of all the great cities of the empire were lighted with oil burnt in lamps, he held that the time was not distant when a carburreted hydrogen gas would be sub-tituted instead ; and, on getting his snug parsonage-honse repaired, he actually introduced into the walls a system of tubes and pipes for the passage into its various rooms of the gaseous fluid yet to be employed as the illuminating agent. Time and experience have since impressed their stamp on these supposed eccentricities, and shown them to be the sagacious forecastings of a man who saw further and more clearly than his contemporaries ; and fame has since blown his name very widely, as one of the most comprehensive and enlightened, and, withal, one of the most thoroughly earnest and sincere, of modern theologians. The bold lecturer of St. Andrews was Dr. Thomas Chalmers,-a divine whose writings are now known wherever the English language is spoken, and whose wonderful eloquence lives in memory as a vanished power, which even his extraordinary writings fail adequately to repre-And in the position which he took up at this early period with respect to sent. geology and the Divine Record, we have yet another instance of the great sagacity of the man, and of his ability of correctly estimating the prevailing weight of the evidence with which, though but partially collected at the time, the geologist was preparing to establish the leading propositions of his science, Even in this late age, when the scientific standing of geology is all but universally recognized, and the vast periods of time which it demands fully conceded, neither geologist nor theologian could, in any new scheme of reconciliation, shape his first proposition more skillfully than it was shaped by Chalmers a full half century ago. It has formed since that time the preliminary proposition of those ornaments of at once Science and the English Church, the present venerable Archbishop of Canterbury, Dr. Bird Summer, with Doctors Buckland, Conybeare, and Professor Sedgwick; of eminent evangelistic Dissenters too, such as the late Dr. Pye Smith, Dr. John Harris, Dr. Robert Vaughan, Dr. James Hamilton, and the Rev, Mr. Binney,-enlightened and distinguished men, who all came early to the conclusion, with the lecturer of St. Andrews, that "the writings of Moses do not fix the antiquity of the globe."

With a view to carry out systematically the object of the work, its two preliminary chapters, or lectures, are devoted to a popular review of the Palaeontology of Plants and Animals; in which, amongst other facts, the relative perfectibility of the great typical groups with the geological advent of these, in clearly and forcibly shown. Upon a track so often traversed, little of actual novelty can, of course, be expected; but the singularly felicitous and graphic

manner in which the teachings of modern science are brought in all their force before the reader, may be gathered from the following quotation, extracted from the opening of the second lecture :---

"Amid the unceasing change and endless variety of Nature there occur certain great radical ideas, that, while they form, if I may so express myself, the groundwork of the change,-the basis of the variety,-admit in themselves of no change or variety whatever. They constitute the ave-enduring tissue on which the everchanging patterns of creation are inscribed: the patterns are ever varying; the tissue which exhibits them for ever remains the same. In the Animal Kingdom for instance, the prominent ideas have always been uniform. However much the faunas of the geologic periods may have differed from each other, or from the fauna which now exists, in their general aspect and character, they were all, if I may so speak, equally underlaid by the great leading ideas which still constitute the master types of animal life. And these leading ideas are four in number. First, there is the star-like type of life,-life embodied in a form that, as in the corals, the sea-anemones, the sea-urchins, and the star-fishes, radiates outwards from a centre; second, there is the arti ulated type of life, -- life embodied in a form composed, as in the worms, crustaceans, and insects, of a series of rings united by their edges, but more or less moveable on each other; third, there is the bilateral or molluscan type of life,-life embodied in a form in which there is a duality of corresponding parts, ranged as in the cuttle-fishes, the clams, and the snails, on the sides of a central axis or plane; and fourth, there is the vertebrate type of life,-life embodied in a form in which an internal skeleton is built up into two cavities placed the one over the other ; the upper for the reception of the nervous centres, cerebal and spinal,-the lower for the lodgment of the respiratory, circulatory, and digestive organs. Such have been the four central ideas of the faunas of every succeeding creation, except perhaps the earliest of all, that of the Lower Silurian System, in which so far as is yet known, only three of the number existed,-the radiated, articulated, and molluscan ideas or types. The Omnipotent Creator, infinite in his resources, -who, in at least the details of his workings, seems never yet to have repeated himself, but, as Lyell well expresses it, breaks when the parents of a species have been moulded, the dye in which they were cast,-manifests himself, in these four great ideas, as the unchanging and unchangeable One. They serve to bind together the present with all the past; and determine the unity of the authorship of a wonderfully complicated design, executed on a groundwork broad as time, and whose scope and bearing are deep as eternity."

After the two preliminary lectures alluded to above, the theological bearings of Geology in many of its leading questions, are taken up and discussed in several lectures with great fearlessness and power. From the known and sterling piety of their gifted author, combined with his equally recognised position in the scientific world, we regard these portions of Hugh Miller's work as peculiarly valuable in their advocacy of the true claims of geological science. It may be that here and there he fails to establish all his arguments in a thoroughly satisfactory manner, but the failure must be sought for in the very nature of the questions touched upon. The main arguments however, the broad views of enlightened science as distinguished from bigoted empiricism on the one hand, and from skepticism on the other, are sustained by his close and varied reasoning, to their full. Were it not that the book must necessarily fall sooner or later into the hands of our readers, we should much regret our inability from want of space, to transcribe a few of the glowing pages belonging to this portion of its contents. In the lecture, more especially, entitled "The Mosaic Vision of Creation," we have a sketch of exceeding beauty, portraying the eventful and stupendous changes of the great geological DAYS, on the supposition that these were revealed to Moses in a series of visions. This idea however does not originate with Hugh Miller, as some of his biographers seem to infer. It has been brought prominently forward of late years by various authors, more particularly by the German Theologians. As our author observes, the visions of Milton's Adam when , by the agency of the Archangel Michael the future was unveiled before him, may have given rise to this beautiful and by no means improbable conception. "Before the eye of the seer," says Professor Kurtz, of Dorpat, "scene after scene may have been unfolded, until at length, in the seven of them, the course of creation in its main momenta was fully represented." The vivid portraiture in the work before us of these wondrous phases in the ancient history of our world, is too long for quotation ; and hence, as a final extract, all that our limited space will allow us to indulge in, we give the following eloquent passage from another lecture :

"Such, so far as the geologist has yet been able to read the records of his science, has been the course of creation, from the first beginnings of vitality upon our planet, until the appearance of man. And very wonderful, surely, has that course been! How strange a procession! Never yet on Egyptian obclisk or Assyrian frieze,—where long lines of figures seem stalking across the granite, each charged with symbol and mystery,—have our Layards or Rawlinsons seen aught so extraordinary as that long procession of Being which, starting out of the blank depths of the by-gone Eternity, is still defiling across the stage, and of which we ourselves form some of the passing figures. Who shall delare the profound meanings with which these geologic hieroglyphics are charged, or indicate the ultimate goal at which the long procession it destined to arrive ?

The readings already given, the conclusions already deduced, are as various as the hopes and fears, the habits of thought, and the cast of intellect, of the several interpreters who have set themselves,—some, alas! with but little preparation and very imperfect knowledge,—to declare in their order the details of this marvellous, dream-like vision, and, with the dream, "the interpretation thereof." One class of interpreters may well remind us of the dim-eyed old man,—the genius of unbelief so poetically described by Coleridge,—who, sitting in his cold and dreary

cave, "talked much and vehemently concerning an infinite series of causes and effects, which he explained to be a string of blind men, the last of whom caught hold of the skirt of the one before him, he of the next, and so on, till they were all out of sight, and that they all walked infallibly straight, without making one false step, though all were alike blind," With these must I class those assertors of the development hypothesis who can see in the upward progress of being only the operations of an incomprehending and incomprehensible law, through which, in the course of unreckoned ages, the lower tribes and families have risen into the higher, and inferior into superior natures, and in virtue of which, in short, the animal creation has grown, in at least its nobler specimens, altogether unwittingly, without thought or care on its own part, and without intelligence on the part of the operating law, from irrational to rational, and risen in the scale from the mere promptings of instinut to the highest exercise of reason,--from apes and baboons to Bacons and Newtons. The blind lead the blind ;- the unseeing law operates on the unperceiving creatures; and they go, not together into the ditch, but direct onwards, straight as an arrow, and higher and higher at every step.

"Another class look with profound melancholy on that great eity of the dead, the burial place of all that ever lived in the past,—which occupies with its everextending pavements of gravestones, and its ever-lengthening streets of tombs and sepulchres, every region opened up by the geologist. They see the onward procession of being as if but tipped with life, and nought but inanimate carcasses all behind,—dead individuals, dead species, dead genera, dead creations,—a universe of death; and ask whether the same annihilation which overtook in turn all the past, shall not onr day overtake our own race also, and a time come when men and their works shall have no existence save as stone-pervaded fossils locked up in the rock forever ? Nowhere do we find the doubts and fears of this class more admirably portrayed than in the works of perhaps the most thoughtful and suggestive of living poets :—

" Are God and Nature then at strife,

That Nature lends such evil dreams? So careful of the type she seems,

So careless of the single life;

'So careful of the type ?' but no,

From scarped cliff and quarried stone,

She cries, 'A thousand types are gone.'

I care for nothing ; all shall go : Thou makest thine appeal to me :

I bring to life, I bring to death:

The spirit does but mean the breath: I know no more.' And he,—shall he, Man, her last work, who seemed so fair,

Such splendid purpose in his eyes,

Who rolled the psalm to wintry skies, And built him fanes of fruitless prayer, Who trusted God was love indeed,

And love creation's final law,

Though Nature, red in tooth and claw, With ravine shrieked against his creed,—

## REVIEWS-THE TESTIMONY OF THE ROCKS.

Who loved, who suffered countless ills,
Who battled for the True, the Just,—
Be blown about the desert dust,
Or sealed within the iron hills ?
No more !—a monster, then, a dream,
A discord. Dragons of the prime,
That tore each other in their slime,
Were mellow music matched with him.
O, life, as futile then as frail,—
O for thy voice to soothe and bless !
What hope of answer or redress :
Behind the veil, behind the veil!"
